The capacity is accompanied by the necessity of providing an adequate transfer of knowledge within the framework of a basis model, which are being loaded into the federated learning environment without subjecting it to a heavy consumption of computationally intensive load. The foundation of web adapt on mobile federated learning is also elaborated to incorporate a balancing of the model structure and training algorithms to be executed using hardcore budgets of resources. It will involve the creation of new solutions in order to quantize and prune optimized to execute on-device inference and federated learning approaches that are able to assist the capabilities of different hardware settings and network circumstances. Such a complicated interaction implies that both the architectural aspects of the foundation models and the limitations of communication of federated mobile environments should be shared broadly to achieve the right accuracy privacy trade-offs. Further bonus plans to attract clients and effective deployment strategies are great in the environmentally friendly platform of the federated foundation model on the wireless field. Speaking more specifically, by using the foundation models and the system of federated learning, we will be capable of performing a more personalized approach and an efficient system of recommendations, by dealing with such concerns as the data sparsity and non-IID distributions of data among the consumers. However, with the integration, new complexities are attached including an effective personalization modelling because of the variety of preferences of the separated clients and effective fusion between collective knowledge of previously trained foundation models and personalization of the users. These complexities lead to issues, and these issues are best addressed by a complex resolution, which is normally a trade-off between the computation problems of large models and privacy protecting on-device learning and efficient knowledge transfer relations in a federated scheme. These methods are usually parameter efficient fine-tuning methods, which can be adapted to the specifics of the individual user, without necessarily doing considerable customization to the large ground model itself. It is a paradigm of teacher-student learning that can be effectively deployed to small devices that belong to clients to utilize the amount of knowledge about the domain of the enormous foundation model. It is a method that is often supported with methods such as knowledge distillation applied in the student model in order to realize causally similar performance with reduced computation costs as opposed to a larger teacher model. It also can be potentially useful in a mobile environment when the computing resources present is minimal; in this case one can have a recommendation system that possesses high capability at levels that do not necessarily overload the available capacity of the device. Besides, parameter-efficient fine-tuning approaches, which can be suggested to supplement quantization approaches like AWQ, can also become a potential solution to running and training these large models on federated networks, which can tackle the technicalities related to the on-device execution. The

 mechanism is additionally effective as it reduces communication overheads in terms of reducing the amount
of data that is transmitted between clients and central server which in turn increases the practicability o
f executing more compilated recommender systems in the background of mobile that has bandwidth limitation.
The federated learning models could be enhanced by adding the foundation models to help improve collaborati
ve filtering through exploiting the immense inductive biases and external knowledge exemplified in FMs and
that has been acquired by examining many massive datasets to provide guidance to more common adaptable comp
onents of the recommendation system. Not only in making good initial recommendation is it addressing the pr
oblem of cold-start, but also in addressing the problem of data sparsity and heterogeneity of distributed m
obile dataset. (Carreira-Perpiñán, 2017; Y. Cheng, 2024; Z. Deng, 2022; Dhaouadi et al., 2025; Duan \u0026

dge about the domain of the enormous foundation model. It is a method that is often supported with methods
such as knowledge distillation applied in the student model in order to realize causally similar performanc
e with reduced computation costs as opposed to a larger teacher model. It also can be potentially useful in
 a mobile environment when the computing resources present is minimal; in this case one can have a recommen
dation system that possesses high capability at levels that do not necessarily overload the available capac
ity of the device. Besides, parameter-efficient fine-tuning approaches, which can be suggested to supplemen
t quantization approaches like AWQ, can also become a potential solution to running and training these larg
e models on federated networks, which can tackle the technicalities related to the on-device execution. The
 mechanism is additionally effective as it reduces communication overheads in terms of reducing the amount
of data that is transmitted between clients and central server which in turn increases the practicability o
f executing more compilated recommender systems in the background of mobile that has bandwidth limitation.
The federated learning models could be enhanced by adding the foundation models to help improve collaborati
ve filtering through exploiting the immense inductive biases and external knowledge exemplified in FMs and
that has been acquired by examining many massive datasets to provide guidance to more common adaptable comp
onents of the recommendation system. Not only in making good initial recommendation is it addressing the pr
oblem of cold-start, but also in addressing the problem of data sparsity and heterogeneity of distributed m
obile dataset. (Carreira-Perpiñán, 2017; Y. Cheng, 2024; Z. Deng, 2022; Dhaouadi et al., 2025; Duan \u0026

The capacity is accompanied by the necessity of providing an adequate transfer of knowledge within the framework of a basis model, which are being loaded into the federated learning environment without subjecting it to a heavy consumption of computationally intensive load. The foundation of web adapt on mobile federated learning is also elaborated to incorporate a balancing of the model structure and training algorithms to be executed using hardcore budgets of resources. It will involve the creation of new solutions in order to quantize and prune optimized to execute on-device inference and federated learning approaches that are able to assist the capabilities of different hardware settings and network circumstances. Such a complicated interaction implies that both the architectural aspects of the foundation models and the limitations of communication of federated mobile environments should be shared broadly to achieve the right accuracy privacy trade-offs. Further bonus plans to attract clients and effective deployment strategies are great in the environmentally friendly platform of the federated foundation model on the wireless field. Speaking more specifically, by using the foundation models and the system of federated learning, we will be capable of performing a more personalized approach and an efficient system of recommendations, by dealing with such concerns as the data sparsity and non-IID distributions of data among the consumers. However, with the integration, new complexities are attached including an effective personalization modelling because of the variety of preferences of the separated clients and effective fusion between collective knowledge of previously trained foundation models and personalization of the users. These complexities lead to issues, and these issues are best addressed by a complex resolution, which is normally a trade-off between the computation problems of large models and privacy protecting on-device learning and efficient knowledge transfer relations in a federated scheme. These methods are usually parameter efficient fine-tuning methods, which can be adapted to the specifics of the individual user, without necessarily doing considerable customization to the large ground model itself. It is a paradigm of teacher-student learning that can be effectively deployed to small devices that belong to clients to utilize the amount of knowledge about the domain of the enormous foundation model. It is a method that is often supported with methods such as knowledge distillation applied in the student model in order to realize causally similar performance with reduced computation costs as opposed to a larger teacher model. It also can be potentially useful in a mobile environment when the computing resources present is minimal; in this case one can have a recommendation system that possesses high capability at levels that do not necessarily overload the available capacity of the device. Besides, parameter-efficient fine-tuning approaches, which can be suggested to supplement quantization approaches like AWQ, can also become a potential solution to running and training these larg

e models on federated networks, which can tackle the technicalities related to the on-device execution. The
 mechanism is additionally effective as it reduces communication overheads in terms of reducing the amount
of data that is transmitted between clients and central server which in turn increases the practicability o
f executing more compilated recommender systems in the background of mobile that has bandwidth limitation.
The federated learning models could be enhanced by adding the foundation models to help improve collaborati
ve filtering through exploiting the immense inductive biases and external knowledge exemplified in FMs and
that has been acquired by examining many massive datasets to provide guidance to more common adaptable comp
onents of the recommendation system. Not only in making good initial recommendation is it addressing the pr
oblem of cold-start, but also in addressing the problem of data sparsity and heterogeneity of distributed m
obile dataset. (Carreira-Perpiñán, 2017; Y. Cheng, 2024; Z. Deng, 2022; Dhaouadi et al., 2025; Duan \u0026

The capacity is accompanied by the necessity of providing an adequate transfer of knowledge within the framework of a basis model, which are being loaded into the federated learning environment without subjecting it to a heavy consumption of computationally intensive load. The foundation of web adapt on mobile federated learning is also elaborated to incorporate a balancing of the model structure and training algorithms to be executed using hardcore budgets of resources. It will involve the creation of new solutions in order to quantize and prune optimized to execute on-device inference and federated learning approaches that are able to assist the capabilities of different hardware settings and network circumstances. Such a complicated interaction implies that both the architectural aspects of the foundation models and the limitations of communication of federated mobile environments should be shared broadly to achieve the right accuracy privacy trade-offs. Further bonus plans to attract clients and effective deployment strategies are great in the environmentally friendly platform of the federated foundation model on the wireless field. Speaking more specifically, by using the foundation models and the system of federated learning, we will be capable of performing a more personalized approach and an efficient system of recommendations, by dealing with such concerns as the data sparsity and non-IID distributions of data among the consumers. However, with the integration, new complexities are attached including an effective personalization modelling because of the variety of preferences of the separated clients and effective fusion between collective knowledge of previously trained foundation models and personalization of the users. These complexities lead to issues, and these issues are best addressed by a complex resolution, which is normally a trade-off between the computation problems of large models and privacy protecting on-device learning and efficient knowledge transfer relations in a federated scheme. These methods are usually parameter efficient fine-tuning methods, which can be adapted to the specifics of the individual user, without necessarily doing considerable customization to the large ground model itself. It is a paradigm of teacher-student learning that can be effectively deployed to small devices that belong to clients to utilize the amount of knowledge about the domain of the enormous foundation model. It is a method that is often supported with methods such as knowledge distillation applied in the student model in order to realize causally similar performance with reduced computation costs as opposed to a larger teacher model. It also can be potentially useful in a mobile environment when the computing resources present is minimal; in this case one can have a recommendation system that possesses high capability at levels that do not necessarily overload the available capacity of the device. Besides, parameter-efficient fine-tuning approaches, which can be suggested to supplement quantization approaches like AWQ, can also become a potential solution to running and training these large models on federated networks, which can tackle the technicalities related to the on-device execution. The mechanism is additionally effective as it reduces communication overheads in terms of reducing the amount of data that is transmitted between clients and central server which in turn increases the practicability of executing more compilated recommender systems in the background of mobile that has bandwidth limitation. The federated learning models could be enhanced by adding the foundation models to help improve collaborative filtering through exploiting the immense inductive biases and external knowledge exemplified in FMs and that has been acquired by examining many massive datasets to provide guidance to more common adaptable components of the recommendation system. Not only in making good initial recommendation is it addressing the problem of cold-start, but also in addressing the problem of data sparsity and heterogeneity of distributed mobile dataset. The capacity is accompanied by the necessity of providing an adequate transfer of knowledge within the framework of a basis model, which are being loaded into the federated learning environment without subjecting it to a heavy consumption of computationally intensive load. The foundation of web adapt on mobile federated learning is also elaborated to incorporate a balancing of the model structure and training algorithms to be executed using hardcore budgets of resources. It will involve the creation of new solutions in order to quantize and prune optimized to execute on-device inference and federated learning approaches that are able to assist the capabilities of different hardware settings and network circumstances. Such a complicated interaction implies that both the architectural aspects of the foundation models and the limitations of communication of federated mobile environments should be shared broadly to achieve the right accuracy privacy trade-offs. Further bonus plans to attract clients and effective deployment strategies are great in the environmentally friendly platform of the federated foundation model on the wireless field. Speaking more specifically, by using the foundation models and the system of federated learning, we will be capable of performing a more personalized approach and an efficient system of recommendations, by dealing with such concerns as the data sparsity and non-IID distributions of data among the consumers. However, with the integration, new complexities are attached including an effective personalization modelling because of the variety of preferences of the separated clients and effective fusion between collective knowledge of previously trained foundation models and personalization of the users. These complexities lead to issues, and these issues are best addressed by a complex resolution, which is normally a trade-off between the computation problems of large models and privacy protecting on-device learning and efficient knowledge transfer relations in a federated scheme. These methods are usually parameter efficient fine-tuning methods, which can be adapted to the specifics of the individual user, without necessarily doing considerable customization to the large ground model itself. It is a paradigm of teacher-student learning that can be effectively deployed to small devices that belong to clients to utilize the amount of knowledge about the domain of the enormous foundation model. It is a method that is often supported with methods such as knowledge distillation applied in the student model in order to realize causally similar performance with reduced computation costs as opposed to a larger teacher model. It also can be potentially useful in a mobile environment when the computing resources present is minimal; in this case one can have a recommendation system that possesses high capability at levels that do not necessarily overload the available capacity of the device. Besides, parameter-efficient fine-tuning approaches, which can be suggested to supplement quantization approaches like AWQ, can also become a potential solution to running and training these large models on federated networks, which can tackle the technicalities related to the on-device execution. The

```
 mechanism is additionally effective as it reduces communication overheads in terms of reducing the amount
of data that is transmitted between clients and central server which in turn increases the practicability o
f executing more compilated recommender systems in the background of mobile that has bandwidth limitation.
The federated learning models could be enhanced by adding the foundation models to help improve collaborati
ve filtering through exploiting the immense inductive biases and external knowledge exemplified in FMs and
that has been acquired by examining many massive datasets to provide guidance to more common adaptable comp
onents of the recommendation system. Not only in making good initial recommendation is it addressing the pr
oblem of cold-start, but also in addressing the problem of data sparsity and heterogeneity of distributed m
obile dataset. (Carreira-Perpiñán, 2017; Y. Cheng, 2024; Z. Deng, 2022; Dhaouadi et al., 2025; Duan \u0026

"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} The way out o
f this is an interesting solution introduced by the highly learned foundation models with high-level semant
ic knowledge that can be utilized to generate good representations of users and items and thus allows zero-
shot and few-shot learning to simplify the process. The capacity is accompanied by the necessity of providi
ng an adequate transfer of knowledge within the framework of a basis model, which are being loaded into the
 federated learning environment without subjecting it to a heavy consumption of computationally intensive l
oad. The foundation of web adapt on mobile federated learning is also elaborated to incorporate a balancing
 of the model structure and training algorithms to be executed using hardcore budgets of resources. It will
 involve the creation of new solutions in order to quantize and prune optimized to execute on-device infere
nce and federated learning approaches that are able to assist the capabilities of different hardware settin
gs and network circumstances. Such a complicated interaction implies that both the architectural aspects of
 the foundation models and the limitations of communication of federated mobile environments should be shar
ed broadly to achieve the right accuracy privacy trade-offs. Further bonus plans to attract clients and eff
ective deployment strategies are great in the environmentally friendly platform of the federated foundation
 model on the wireless field. Speaking more specifically, by using the foundation models and the system of
federated learning, we will be capable of performing a more personalized approach and an efficient system o
f recommendations, by dealing with such concerns as the data sparsity and non-IID distributions of data amo
ng the consumers. However, with the integration, new complexities are attached including an effective perso
nalization modelling because of the variety of preferences of the separated clients and effective fusion be
tween collective knowledge of previously trained foundation models and personalization of the users. These
complexities lead to issues, and these issues are best addressed by a complex resolution, which is normally
 a trade-off between the computation problems of large models and privacy protecting on-device learning and
 efficient knowledge transfer relations in a federated scheme. These methods are usually parameter efficien
t fine-tuning methods, which can be adapted to the specifics of the individual user, without necessarily do
ing considerable customization to the large ground model itself. It is a paradigm of teacher-student learni
ng that can be effectively deployed to small devices that belong to clients to utilize the amount of knowle
dge about the domain of the enormous foundation model. It is a method that is often supported with methods
such as knowledge distillation applied in the student model in order to realize causally similar performanc
e with reduced computation costs as opposed to a larger teacher model. It also can be potentially useful in
 a mobile environment when the computing resources present is minimal; in this case one can have a recommen
dation system that possesses high capability at levels that do not necessarily overload the available capac
ity of the device. Besides, parameter-efficient fine-tuning approaches, which can be suggested to supplemen
t quantization approaches like AWQ, can also become a potential solution to running and training these larg
e models on federated networks, which can tackle the technicalities related to the on-device execution. The
 mechanism is additionally effective as it reduces communication overheads in terms of reducing the amount
of data that is transmitted between clients and central server which in turn increases the practicability o
f executing more compilated recommender systems in the background of mobile that has bandwidth limitation.
The federated learning models could be enhanced by adding the foundation models to help improve collaborati
ve filtering through exploiting the immense inductive biases and external knowledge exemplified in FMs and
that has been acquired by examining many massive datasets to provide guidance to more common adaptable comp
onents of the recommendation system. Not only in making good initial recommendation is it addressing the pr
oblem of cold-start, but also in addressing the problem of data sparsity and heterogeneity of distributed m
obile dataset. (Carreira-Perpiñán, 2017; Y. Cheng, 2024; Z. Deng, 2022; Dhaouadi et al., 2025; Duan \u0026

"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} The way out o
f this is an interesting solution introduced by the highly learned foundation models with high-level semant
ic knowledge that can be utilized to generate good representations of users and items and thus allows zero-
shot and few-shot learning to simplify the process. The capacity is accompanied by the necessity of providi
ng an adequate transfer of knowledge within the framework of a basis model, which are being loaded into the
 federated learning environment without subjecting it to a heavy consumption of computationally intensive l
oad. The foundation of web adapt on mobile federated learning is also elaborated to incorporate a balancing
 of the model structure and training algorithms to be executed using hardcore budgets of resources. It will
 involve the creation of new solutions in order to quantize and prune optimized to execute on-device infere
nce and federated learning approaches that are able to assist the capabilities of different hardware settin
gs and network circumstances. Such a complicated interaction implies that both the architectural aspects of
 the foundation models and the limitations of communication of federated mobile environments should be shar
ed broadly to achieve the right accuracy privacy trade-offs. Further bonus plans to attract clients and eff
ective deployment strategies are great in the environmentally friendly platform of the federated foundation
 model on the wireless field. Speaking more specifically, by using the foundation models and the system of
federated learning, we will be capable of performing a more personalized approach and an efficient system o
f recommendations, by dealing with such concerns as the data sparsity and non-IID distributions of data amo
ng the consumers. However, with the integration, new complexities are attached including an effective perso
nalization modelling because of the variety of preferences of the separated clients and effective fusion be
tween collective knowledge of previously trained foundation models and personalization of the users. These
complexities lead to issues, and these issues are best addressed by a complex resolution, which is normally
 a trade-off between the computation problems of large models and privacy protecting on-device learning and
 efficient knowledge transfer relations in a federated scheme. These methods are usually parameter efficien
t fine-tuning methods, which can be adapted to the specifics of the individual user, without necessarily do
ing considerable customization to the large ground model itself. It is a paradigm of teacher-student learni
ng that can be effectively deployed to small devices that belong to clients to utilize the amount of knowle
dge about the domain of the enormous foundation model. It is a method that is often supported with methods
such as knowledge distillation applied in the student model in order to realize causally similar performanc
e with reduced computation costs as opposed to a larger teacher model. It also can be potentially useful in
 a mobile environment when the computing resources present is minimal; in this case one can have a recommen
dation system that possesses high capability at levels that do not necessarily overload the available capac
ity of the device. Besides, parameter-efficient fine-tuning approaches, which can be suggested to supplemen
t quantization approaches like AWQ, can also become a potential solution to running and training these larg
e models on federated networks, which can tackle the technicalities related to the on-device execution. The
 mechanism is additionally effective as it reduces communication overheads in terms of reducing the amount
of data that is transmitted between clients and central server which in turn increases the practicability o
f executing more compilated recommender systems in the background of mobile that has bandwidth limitation.
The federated learning models could be enhanced by adding the foundation models to help improve collaborati
ve filtering through exploiting the immense inductive biases and external knowledge exemplified in FMs and
that has been acquired by examining many massive datasets to provide guidance to more common adaptable comp
onents of the recommendation system. Not only in making good initial recommendation is it addressing the pr
oblem of cold-start, but also in addressing the problem of data sparsity and heterogeneity of distributed m
obile dataset. (Carreira-Perpiñán, 2017; Y. Cheng, 2024; Z. Deng, 2022; Dhaouadi et al., 2025; Duan \u0026

The capacity is accompanied by the necessity of providing an adequate transfer of knowledge within the framework of a basis model, which are being loaded into the federated learning environment without subjecting it to a heavy consumption of computationally intensive load. The foundation of web adapt on mobile federated learning is also elaborated to incorporate a balancing of the model structure and training algorithms to be executed using hardcore budgets of resources. It will involve the creation of new solutions in order to quantize and prune optimized to execute on-device inference and federated learning approaches that are able to assist the capabilities of different hardware settings and network circumstances. Such a complicated interaction implies that both the architectural aspects of the foundation models and the limitations of communication of federated mobile environments should be shared broadly to achieve the right accuracy privacy trade-offs. Further bonus plans to attract clients and effective deployment strategies are great in the environmentally friendly platform of the federated foundation model on the wireless field. Speaking more specifically, by using the foundation models and the system of federated learning, we will be capable of performing a more personalized approach and an efficient system of recommendations, by dealing with such concerns as the data sparsity and non-IID distributions of data among the consumers. However, with the integration, new complexities are attached including an effective personalization modelling because of the variety of preferences of the separated clients and effective fusion between collective knowledge of previously trained foundation models and personalization of the users. These complexities lead to issues, and these issues are best addressed by a complex resolution, which is normally a trade-off between the computation problems of large models and privacy protecting on-device learning and efficient knowledge transfer relations in a federated scheme. These methods are usually parameter efficient fine-tuning methods, which can be adapted to the specifics of the individual user, without necessarily doing considerable customization to the large ground model itself. It is a paradigm of teacher-student learni

ng that can be effectively deployed to small devices that belong to clients to utilize the amount of knowle
dge about the domain of the enormous foundation model. It is a method that is often supported with methods
such as knowledge distillation applied in the student model in order to realize causally similar performanc
e with reduced computation costs as opposed to a larger teacher model. It also can be potentially useful in
 a mobile environment when the computing resources present is minimal; in this case one can have a recommen
dation system that possesses high capability at levels that do not necessarily overload the available capac
ity of the device. Besides, parameter-efficient fine-tuning approaches, which can be suggested to supplemen
t quantization approaches like AWQ, can also become a potential solution to running and training these larg
e models on federated networks, which can tackle the technicalities related to the on-device execution. The
 mechanism is additionally effective as it reduces communication overheads in terms of reducing the amount
of data that is transmitted between clients and central server which in turn increases the practicability o
f executing more compilated recommender systems in the background of mobile that has bandwidth limitation.
The federated learning models could be enhanced by adding the foundation models to help improve collaborati
ve filtering through exploiting the immense inductive biases and external knowledge exemplified in FMs and
that has been acquired by examining many massive datasets to provide guidance to more common adaptable comp
onents of the recommendation system. Not only in making good initial recommendation is it addressing the pr
oblem of cold-start, but also in addressing the problem of data sparsity and heterogeneity of distributed m
obile dataset. (Carreira-Perpiñán, 2017; Y. Cheng, 2024; Z. Deng, 2022; Dhaouadi et al., 2025; Duan \u0026

The capacity is accompanied by the necessity of providing an adequate transfer of knowledge within the framework of a basis model, which are being loaded into the federated learning environment without subjecting it to a heavy consumption of computationally intensive load. The foundation of web adapt on mobile federated learning is also elaborated to incorporate a balancing of the model structure and training algorithms to be executed using hardcore budgets of resources. It will involve the creation of new solutions in order to quantize and prune optimized to execute on-device inference and federated learning approaches that are able to assist the capabilities of different hardware settings and network circumstances. Such a complicated interaction implies that both the architectural aspects of the foundation models and the limitations of communication of federated mobile environments should be shared broadly to achieve the right accuracy privacy trade-offs. Further bonus plans to attract clients and effective deployment strategies are great in the environmentally friendly platform of the federated foundation model on the wireless field. Speaking more specifically, by using the foundation models and the system of federated learning, we will be capable of performing a more personalized approach and an efficient system of recommendations, by dealing with such concerns as the data sparsity and non-IID distributions of data among the consumers. However, with the integration, new complexities are attached including an effective personalization modelling because of the variety of preferences of the separated clients and effective fusion between collective knowledge of previously trained foundation models and personalization of the users. These complexities lead to issues, and these issues are best addressed by a complex resolution, which is normally a trade-off between the computation problems of large models and privacy protecting on-device learning and efficient knowledge transfer relations in a federated scheme. These methods are usually parameter efficient fine-tuning methods, which can be adapted to the specifics of the individual user, without necessarily doing considerable customization to the large ground model itself. It is a paradigm of teacher-student learning that can be effectively deployed to small devices that belong to clients to utilize the amount of knowledge about the domain of the enormous foundation model. It is a method that is often supported with methods such as knowledge distillation applied in the student model in order to realize causally similar performance with reduced computation costs as opposed to a larger teacher model. It also can be potentially useful in a mobile environment when the computing resources present is minimal; in this case one can have a recommendation system that possesses high capability at levels that do not necessarily overload the available capacity of the device. Besides, parameter-efficient fine-tuning approaches, which can be suggested to supplement quantization approaches like AWQ, can also become a potential solution to running and training these large models on federated networks, which can tackle the technicalities related to the on-device execution. The mechanism is additionally effective as it reduces communication overheads in terms of reducing the amount of data that is transmitted between clients and central server which in turn increases the practicability of executing more compilated recommender systems in the background of mobile that has bandwidth limitation. The federated learning models could be enhanced by adding the foundation models to help improve collaborative filtering through exploiting the immense inductive biases and external knowledge exemplified in FMs and that has been acquired by examining many massive datasets to provide guidance to more common adaptable components of the recommendation system. Not only in making good initial recommendation is it addressing the problem of cold-start, but also in addressing the problem of data sparsity and heterogeneity of distributed mobile dataset. The capacity is accompanied by the necessity of providing an adequate transfer of knowledge within the framework of a basis model, which are being loaded into the federated learning environment without subjecting it to a heavy consumption of computationally intensive load. The foundation of web adapt on mobile federated learning is also elaborated to incorporate a balancing of the model structure and training algorithms to be executed using hardcore budgets of resources. It will involve the creation of new solutions in order to quantize and prune optimized to execute on-device inference and federated learning approaches that are able to assist the capabilities of different hardware settings and network circumstances. Such a complicated interaction implies that both the architectural aspects of the foundation models and the limitations of communication of federated mobile environments should be shared broadly to achieve the right accuracy privacy trade-offs. Further bonus plans to attract clients and effective deployment strategies are great in the environmentally friendly platform of the federated foundation model on the wireless field. Speaking more specifically, by using the foundation models and the system of federated learning, we will be capable of performing a more personalized approach and an efficient system of recommendations, by dealing with such concerns as the data sparsity and non-IID distributions of data among the consumers. However, with the integration, new complexities are attached including an effective personalization modelling because of the variety of preferences of the separated clients and effective fusion between collective knowledge of previously trained foundation models and personalization of the users. These complexities lead to issues, and these issues are best addressed by a complex resolution, which is normally a trade-off between the computation problems of large models and privacy protecting on-device learning and efficient knowledge transfer relations in a federated scheme. These methods are usually parameter efficient fine-tuning methods, which can be adapted to the specifics of the individual user, without necessarily doing considerable customization to the large ground model itself. It is a paradigm of teacher-student learning that can be effectively deployed to small devices that belong to clients to utilize the amount of knowledge about the domain of the enormous foundation model. It is a method that is often supported with methods such as knowledge distillation applied in the student model in order to realize causally similar performance with reduced computation costs as opposed to a larger teacher model. It also can be potentially useful in a mobile environment when the computing resources present is minimal; in this case one can have a recommendation system that possesses high capability at levels that do not necessarily overload the available capacity of the device. Besides, parameter-efficient fine-tuning approaches, which can be suggested to supplement quantization approaches like AWQ, can also become a potential solution to running and training these large models on federated networks, which can tackle the technicalities related to the on-device execution. The mechanism is additionally effective as it reduces communication overheads in terms of reducing the amount of data that is transmitted between clients and central server which in turn increases the practicability of executing more compilated recommender systems in the background of mobile that has bandwidth limitation. The federated learning models could be enhanced by adding the foundation models to help improve collaborative filtering through exploiting the immense inductive biases and external knowledge exemplified in FMs and that has been acquired by examining many massive datasets to provide guidance to more common adaptable components of the recommendation system. Not only in making good initial recommendation is it addressing the problem of cold-start, but also in addressing the problem of data sparsity and heterogeneity of distributed mobile dataset. The capacity is accompanied by the necessity of providing an adequate transfer of knowledge within the framework of a basis model, which are being loaded into the federated learning environment without subjecting it to a heavy consumption of computationally intensive load. The foundation of web adapt on mobile federated learning is also elaborated to incorporate a balancing of the model structure and training algorithms to be executed using hardcore budgets of resources. It will involve the creation of new solutions in order to quantize and prune optimized to execute on-device inference and federated learning approaches that are able to assist the capabilities of different hardware settings and network circumstances. Such a complicated interaction implies that both the architectural aspects of the foundation models and the limitations of communication of federated mobile environments should be shared broadly to achieve the right accuracy privacy trade-offs. Further bonus plans to attract clients and effective deployment strategies are great in the environmentally friendly platform of the federated foundation model on the wireless field. Speaking more specifically, by using the foundation models and the system of federated learning, we will be capable of performing a more personalized approach and an efficient system of recommendations, by dealing with such concerns as the data sparsity and non-IID distributions of data among the consumers. However, with the integration, new complexities are attached including an effective personalization modelling because of the variety of preferences of the separated clients and effective fusion between collective knowledge of previously trained foundation models and personalization of the users. These complexities lead to issues, and these issues are best addressed by a complex resolution, which is normally a trade-off between the computation problems of large models and privacy protecting on-device learning and efficient knowledge transfer relations in a federated scheme. These methods are usually parameter efficient fine-tuning methods, which can be adapted to the specifics of the individual user, without necessarily doing considerable customization to the large ground model itself. It is a paradigm of teacher-student learning that can be effectively deployed to small devices that belong to clients to utilize the amount of knowledge about the domain of the enormous foundation model. It is a method that is often supported with methods such as knowledge distillation applied in the student model in order to realize causally similar performance with reduced computation costs as opposed to a larger teacher model. It also can be potentially useful in a mobile environment when the computing resources present is minimal; in this case one can have a recommendation system that possesses high capability at levels that do not necessarily overload the available capacity of the device. Besides, parameter-efficient fine-tuning approaches, which can be suggested to supplement quantization approaches like AWQ, can also become a potential solution to running and training these larg

```
e models on federated networks, which can tackle the technicalities related to the on-device execution. The
 mechanism is additionally effective as it reduces communication overheads in terms of reducing the amount
of data that is transmitted between clients and central server which in turn increases the practicability o
f executing more compilated recommender systems in the background of mobile that has bandwidth limitation.
The federated learning models could be enhanced by adding the foundation models to help improve collaborati
ve filtering through exploiting the immense inductive biases and external knowledge exemplified in FMs and
that has been acquired by examining many massive datasets to provide guidance to more common adaptable comp
onents of the recommendation system. Not only in making good initial recommendation is it addressing the pr
oblem of cold-start, but also in addressing the problem of data sparsity and heterogeneity of distributed m
obile dataset. (Carreira-Perpiñán, 2017; Y. Cheng, 2024; Z. Deng, 2022; Dhaouadi et al., 2025; Duan \u0026

",\"title\":\"Deep Hybrid Compression Network for Lidar Point Cloud Classification and Segmentation\",\"author\":[{\"family\":\"Zhao\",\"given\":\"Zhi\"},{\"family\":\"Ma\",\"given\":\"Yanxin\"},{\"family\":\"Xu\",\"given\":\"Ke\"},{\"family\":\"Wan\",\"given\":\"Jianwei\"}],\"issued\":{\"date-parts\":[[\"2023\"]]}}}],\"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} The way out of this is an interesting solution introduced by the highly learned foundation models with high-level semantic knowledge that can be utilized to generate good representations of users and items and thus allows zero-shot and few-shot learning to simplify the process. The capacity is accompanied by the necessity of providing an adequate transfer of knowledge within the framework of a basis model, which are being loaded into the federated learning environment without subjecting it to a heavy consumption of computationally intensive load. The foundation of web adapt on mobile federated learning is also elaborated to incorporate a balancing of the model structure and training algorithms to be executed using hardcore budgets of resources. It will involve the creation of new solutions in order to quantize and prune optimized to execute on-device inference and federated learning approaches that are able to assist the capabilities of different hardware settings and network circumstances. Such a complicated interaction implies that both the architectural aspects of the foundation models and the limitations of communication of federated mobile environments should be shared broadly to achieve the right accuracy privacy trade-offs. Further bonus plans to attract clients and effective deployment strategies are great in the environmentally friendly platform of the federated foundation model on the wireless field. Speaking more specifically, by using the foundation models and the system of federated learning, we will be capable of performing a more personalized approach and an efficient system of recommendations, by dealing with such concerns as the data sparsity and non-IID distributions of data among the consumers. However, with the integration, new complexities are attached including an effective personalization modelling because of the variety of preferences of the separated clients and effective fusion between collective knowledge of previously trained foundation models and personalization of the users. These complexities lead to issues, and these issues are best addressed by a complex resolution, which is normally a trade-off between the computation problems of large models and privacy protecting on-device learning and efficient knowledge transfer relations in a federated scheme. These methods are usually parameter efficient fine-tuning methods, which can be adapted to the specifics of the individual user, without necessarily doing considerable customization to the large ground model itself. It is a paradigm of teacher-student learning that can be effectively deployed to small devices that belong to clients to utilize the amount of knowledge about the domain of the enormous foundation model. It is a method that is often supported with methods such as knowledge distillation applied in the student model in order to realize causally similar performance with reduced computation costs as opposed to a larger teacher model. It also can be potentially useful in a mobile environment when the computing resources present is minimal; in this case one can have a recommendation system that possesses high capability at levels that do not necessarily overload the available capacity of the device. Besides, parameter-efficient fine-tuning approaches, which can be suggested to supplement quantization approaches like AWQ, can also become a potential solution to running and training these large models on federated networks, which can tackle the technicalities related to the on-device execution. The mechanism is additionally effective as it reduces communication overheads in terms of reducing the amount of data that is transmitted between clients and central server which in turn increases the practicability of executing more compilated recommender systems in the background of mobile that has bandwidth limitation. The federated learning models could be enhanced by adding the foundation models to help improve collaborative filtering through exploiting the immense inductive biases and external knowledge exemplified in FMs and that has been acquired by examining many massive datasets to provide guidance to more common adaptable components of the recommendation system. Not only in making good initial recommendation is it addressing the problem of cold-start, but also in addressing the problem of data sparsity and heterogeneity of distributed mobile dataset. "schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} The way out o
f this is an interesting solution introduced by the highly learned foundation models with high-level semant
ic knowledge that can be utilized to generate good representations of users and items and thus allows zero-
shot and few-shot learning to simplify the process. The capacity is accompanied by the necessity of providi
ng an adequate transfer of knowledge within the framework of a basis model, which are being loaded into the
 federated learning environment without subjecting it to a heavy consumption of computationally intensive l
oad. The foundation of web adapt on mobile federated learning is also elaborated to incorporate a balancing
 of the model structure and training algorithms to be executed using hardcore budgets of resources. It will
 involve the creation of new solutions in order to quantize and prune optimized to execute on-device infere
nce and federated learning approaches that are able to assist the capabilities of different hardware settin
gs and network circumstances. Such a complicated interaction implies that both the architectural aspects of
 the foundation models and the limitations of communication of federated mobile environments should be shar
ed broadly to achieve the right accuracy privacy trade-offs. Further bonus plans to attract clients and eff
ective deployment strategies are great in the environmentally friendly platform of the federated foundation
 model on the wireless field. Speaking more specifically, by using the foundation models and the system of
federated learning, we will be capable of performing a more personalized approach and an efficient system o
f recommendations, by dealing with such concerns as the data sparsity and non-IID distributions of data amo
ng the consumers. However, with the integration, new complexities are attached including an effective perso
nalization modelling because of the variety of preferences of the separated clients and effective fusion be
tween collective knowledge of previously trained foundation models and personalization of the users. These
complexities lead to issues, and these issues are best addressed by a complex resolution, which is normally
 a trade-off between the computation problems of large models and privacy protecting on-device learning and
 efficient knowledge transfer relations in a federated scheme. These methods are usually parameter efficien
t fine-tuning methods, which can be adapted to the specifics of the individual user, without necessarily do
ing considerable customization to the large ground model itself. It is a paradigm of teacher-student learni
ng that can be effectively deployed to small devices that belong to clients to utilize the amount of knowle
dge about the domain of the enormous foundation model. It is a method that is often supported with methods
such as knowledge distillation applied in the student model in order to realize causally similar performanc
e with reduced computation costs as opposed to a larger teacher model. It also can be potentially useful in
 a mobile environment when the computing resources present is minimal; in this case one can have a recommen
dation system that possesses high capability at levels that do not necessarily overload the available capac
ity of the device. Besides, parameter-efficient fine-tuning approaches, which can be suggested to supplemen
t quantization approaches like AWQ, can also become a potential solution to running and training these larg
e models on federated networks, which can tackle the technicalities related to the on-device execution. The
 mechanism is additionally effective as it reduces communication overheads in terms of reducing the amount
of data that is transmitted between clients and central server which in turn increases the practicability o
f executing more compilated recommender systems in the background of mobile that has bandwidth limitation.
The federated learning models could be enhanced by adding the foundation models to help improve collaborati
ve filtering through exploiting the immense inductive biases and external knowledge exemplified in FMs and
that has been acquired by examining many massive datasets to provide guidance to more common adaptable comp
onents of the recommendation system. Not only in making good initial recommendation is it addressing the pr
oblem of cold-start, but also in addressing the problem of data sparsity and heterogeneity of distributed m
obile dataset. (Carreira-Perpiñán, 2017; Y. Cheng, 2024; Z. Deng, 2022; Dhaouadi et al., 2025; Duan \u0026

"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} The way out o
f this is an interesting solution introduced by the highly learned foundation models with high-level semant
ic knowledge that can be utilized to generate good representations of users and items and thus allows zero-
shot and few-shot learning to simplify the process. The capacity is accompanied by the necessity of providi
ng an adequate transfer of knowledge within the framework of a basis model, which are being loaded into the
 federated learning environment without subjecting it to a heavy consumption of computationally intensive l
oad. The foundation of web adapt on mobile federated learning is also elaborated to incorporate a balancing
 of the model structure and training algorithms to be executed using hardcore budgets of resources. It will
 involve the creation of new solutions in order to quantize and prune optimized to execute on-device infere
nce and federated learning approaches that are able to assist the capabilities of different hardware settin
gs and network circumstances. Such a complicated interaction implies that both the architectural aspects of
 the foundation models and the limitations of communication of federated mobile environments should be shar
ed broadly to achieve the right accuracy privacy trade-offs. Further bonus plans to attract clients and eff
ective deployment strategies are great in the environmentally friendly platform of the federated foundation
 model on the wireless field. Speaking more specifically, by using the foundation models and the system of
federated learning, we will be capable of performing a more personalized approach and an efficient system o
f recommendations, by dealing with such concerns as the data sparsity and non-IID distributions of data amo
ng the consumers. However, with the integration, new complexities are attached including an effective perso
nalization modelling because of the variety of preferences of the separated clients and effective fusion be
tween collective knowledge of previously trained foundation models and personalization of the users. These
complexities lead to issues, and these issues are best addressed by a complex resolution, which is normally
 a trade-off between the computation problems of large models and privacy protecting on-device learning and
 efficient knowledge transfer relations in a federated scheme. These methods are usually parameter efficien
t fine-tuning methods, which can be adapted to the specifics of the individual user, without necessarily do
ing considerable customization to the large ground model itself. It is a paradigm of teacher-student learni
ng that can be effectively deployed to small devices that belong to clients to utilize the amount of knowle
dge about the domain of the enormous foundation model. It is a method that is often supported with methods
 such as knowledge distillation applied in the student model in order to realize causally similar performanc
e with reduced computation costs as opposed to a larger teacher model. It also can be potentially useful in
 a mobile environment when the computing resources present is minimal; in this case one can have a recommen
dation system that possesses high capability at levels that do not necessarily overload the available capac

ity of the device. Besides, parameter-efficient fine-tuning approaches, which can be suggested to supplemen
t quantization approaches like AWQ, can also become a potential solution to running and training these larg
e models on federated networks, which can tackle the technicalities related to the on-device execution. The
 mechanism is additionally effective as it reduces communication overheads in terms of reducing the amount
of data that is transmitted between clients and central server which in turn increases the practicability o
f executing more compilated recommender systems in the background of mobile that has bandwidth limitation.
The federated learning models could be enhanced by adding the foundation models to help improve collaborati
ve filtering through exploiting the immense inductive biases and external knowledge exemplified in FMs and
that has been acquired by examining many massive datasets to provide guidance to more common adaptable comp
onents of the recommendation system. Not only in making good initial recommendation is it addressing the pr
oblem of cold-start, but also in addressing the problem of data sparsity and heterogeneity of distributed m
obile dataset. (Carreira-Perpiñán, 2017; Y. Cheng, 2024; Z. Deng, 2022; Dhaouadi et al., 2025; Duan \u0026

"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} The way out o
f this is an interesting solution introduced by the highly learned foundation models with high-level semant
ic knowledge that can be utilized to generate good representations of users and items and thus allows zero-
shot and few-shot learning to simplify the process. The capacity is accompanied by the necessity of providi
ng an adequate transfer of knowledge within the framework of a basis model, which are being loaded into the
 federated learning environment without subjecting it to a heavy consumption of computationally intensive l
oad. The foundation of web adapt on mobile federated learning is also elaborated to incorporate a balancing
 of the model structure and training algorithms to be executed using hardcore budgets of resources. It will
 involve the creation of new solutions in order to quantize and prune optimized to execute on-device infere
nce and federated learning approaches that are able to assist the capabilities of different hardware settin
gs and network circumstances. Such a complicated interaction implies that both the architectural aspects of
 the foundation models and the limitations of communication of federated mobile environments should be shar
ed broadly to achieve the right accuracy privacy trade-offs. Further bonus plans to attract clients and eff
ective deployment strategies are great in the environmentally friendly platform of the federated foundation
 model on the wireless field. Speaking more specifically, by using the foundation models and the system of
federated learning, we will be capable of performing a more personalized approach and an efficient system o
f recommendations, by dealing with such concerns as the data sparsity and non-IID distributions of data amo
ng the consumers. However, with the integration, new complexities are attached including an effective perso
nalization modelling because of the variety of preferences of the separated clients and effective fusion be
tween collective knowledge of previously trained foundation models and personalization of the users. These
complexities lead to issues, and these issues are best addressed by a complex resolution, which is normally
 a trade-off between the computation problems of large models and privacy protecting on-device learning and
 efficient knowledge transfer relations in a federated scheme. These methods are usually parameter efficien
t fine-tuning methods, which can be adapted to the specifics of the individual user, without necessarily do
ing considerable customization to the large ground model itself. It is a paradigm of teacher-student learni
ng that can be effectively deployed to small devices that belong to clients to utilize the amount of knowle
dge about the domain of the enormous foundation model. It is a method that is often supported with methods
such as knowledge distillation applied in the student model in order to realize causally similar performanc
e with reduced computation costs as opposed to a larger teacher model. It also can be potentially useful in
 a mobile environment when the computing resources present is minimal; in this case one can have a recommen
dation system that possesses high capability at levels that do not necessarily overload the available capac
ity of the device. Besides, parameter-efficient fine-tuning approaches, which can be suggested to supplemen
t quantization approaches like AWQ, can also become a potential solution to running and training these larg
e models on federated networks, which can tackle the technicalities related to the on-device execution. The
 mechanism is additionally effective as it reduces communication overheads in terms of reducing the amount
of data that is transmitted between clients and central server which in turn increases the practicability o
f executing more compilated recommender systems in the background of mobile that has bandwidth limitation.
The federated learning models could be enhanced by adding the foundation models to help improve collaborati
ve filtering through exploiting the immense inductive biases and external knowledge exemplified in FMs and
that has been acquired by examining many massive datasets to provide guidance to more common adaptable comp
onents of the recommendation system. Not only in making good initial recommendation is it addressing the pr
oblem of cold-start, but also in addressing the problem of data sparsity and heterogeneity of distributed m
obile dataset. (Carreira-Perpiñán, 2017; Y. Cheng, 2024; Z. Deng, 2022; Dhaouadi et al., 2025; Duan \u0026

The capacity is accompanied by the necessity of providing an adequate transfer of knowledge within the framework of a basis model, which are being loaded into the federated learning environment without subjecting it to a heavy consumption of computationally intensive load. The foundation of web adapt on mobile federated learning is also elaborated to incorporate a balancing of the model structure and training algorithms to be executed using hardcore budgets of resources. It will involve the creation of new solutions in order to quantize and prune optimized to execute on-device inference and federated learning approaches that are able to assist the capabilities of different hardware settings and network circumstances. Such a complicated interaction implies that both the architectural aspects of the foundation models and the limitations of communication of federated mobile environments should be shared broadly to achieve the right accuracy privacy trade-offs. Further bonus plans to attract clients and effective deployment strategies are great in the environmentally friendly platform of the federated foundation model on the wireless field. Speaking more specifically, by using the foundation models and the system of federated learning, we will be capable of performing a more personalized approach and an efficient system of recommendations, by dealing with such concerns as the data sparsity and non-IID distributions of data among the consumers. However, with the integration, new complexities are attached including an effective personalization modelling because of the variety of preferences of the separated clients and effective fusion between collective knowledge of previously trained foundation models and personalization of the users. These complexities lead to issues, and these issues are best addressed by a complex resolution, which is normally a trade-off between the computation problems of large models and privacy protecting on-device learning and efficient knowledge transfer relations in a federated scheme. These methods are usually parameter efficient fine-tuning methods, which can be adapted to the specifics of the individual user, without necessarily doing considerable customization to the large ground model itself. It is a paradigm of teacher-student learning that can be effectively deployed to small devices that belong to clients to utilize the amount of knowledge about the domain of the enormous foundation model. It is a method that is often supported with methods such as knowledge distillation applied in the student model in order to realize causally similar performance with reduced computation costs as opposed to a larger teacher model. It also can be potentially useful in a mobile environment when the computing resources present is minimal; in this case one can have a recommendation system that possesses high capability at levels that do not necessarily overload the available capacity of the device. Besides, parameter-efficient fine-tuning approaches, which can be suggested to supplement quantization approaches like AWQ, can also become a potential solution to running and training these larg

```
e models on federated networks, which can tackle the technicalities related to the on-device execution. The
 mechanism is additionally effective as it reduces communication overheads in terms of reducing the amount
of data that is transmitted between clients and central server which in turn increases the practicability o
f executing more compilated recommender systems in the background of mobile that has bandwidth limitation.
The federated learning models could be enhanced by adding the foundation models to help improve collaborati
ve filtering through exploiting the immense inductive biases and external knowledge exemplified in FMs and
that has been acquired by examining many massive datasets to provide guidance to more common adaptable comp
onents of the recommendation system. Not only in making good initial recommendation is it addressing the pr
oblem of cold-start, but also in addressing the problem of data sparsity and heterogeneity of distributed m
obile dataset. (Carreira-Perpiñán, 2017; Y. Cheng, 2024; Z. Deng, 2022; Dhaouadi et al., 2025; Duan \u0026

They are commonly constructed when the information that is being used is an inhomogeneous set of users, and when exploited irresponsibly can be known to produce misguided suggestions, or even cause a performance decline because behaviour or interests of a user in various aspects are not matched. To mitigate such risks, new federated systems are based on high parameter-efficient ahead of time tuning, including adapter-based tuning and prompt-based tuning. In this specific instance, these special techniques are designed to only scale the smaller percentage of parameter model (e.g. lightweight adapters, or prompt vectors), and thus cause an enormous decrease in both the costs of communication and computation. It is specifically applicable in privacy-sensitive federated solutions whereby, it minimizes the number of information that is exchanged among client-specific devices and central servers, as well, it also renders the user information more secure on an individual basis. "schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} Nevertheless,
 the federated adaptation is only successful in hybrid approach the art of biological continuous updating a
nd amalgamating the already obtained user embeddings. They are commonly constructed when the information th
at is being used is an inhomogeneous set of users, and when exploited irresponsibly can be known to produce
 misguided suggestions, or even cause a performance decline because behaviour or interests of a user in var
ious aspects are not matched. To mitigate such risks, new federated systems are based on high parameter-eff
icient ahead of time tuning, including adapter-based tuning and prompt-based tuning. In this specific insta
nce, these special techniques are designed to only scale the smaller percentage of parameter model (e.g. li
ghtweight adapters, or prompt vectors), and thus cause an enormous decrease in both the costs of communicat
ion and computation. It is specifically applicable in privacy-sensitive federated solutions whereby, it min
imizes the number of information that is exchanged among client-specific devices and central servers, as we
ll, it also renders the user information more secure on an individual basis. (Carreira-Perpiñán, 2017; Y. C

They are commonly constructed when the information that is being used is an inhomogeneous set of users, and when exploited irresponsibly can be known to produce misguided suggestions, or even cause a performance decline because behaviour or interests of a user in various aspects are not matched. To mitigate such risks, new federated systems are based on high parameter-efficient ahead of time tuning, including adapter-based tuning and prompt-based tuning. In this specific instance, these special techniques are designed to only scale the smaller percentage of parameter model (e.g. lightweight adapters, or prompt vectors), and thus cause an enormous decrease in both the costs of communication and computation. It is specifically applicable in privacy-sensitive federated solutions whereby, it minimizes the number of information that is exchanged among client-specific devices and central servers, as well, it also renders the user information more secure on an individual basis. They are commonly constructed when the information that is being used is an inhomogeneous set of users, and when exploited irresponsibly can be known to produce misguided suggestions, or even cause a performance decline because behaviour or interests of a user in various aspects are not matched. To mitigate such risks, new federated systems are based on high parameter-efficient ahead of time tuning, including adapter-based tuning and prompt-based tuning. In this specific instance, these special techniques are designed to only scale the smaller percentage of parameter model (e.g. lightweight adapters, or prompt vectors), and thus cause an enormous decrease in both the costs of communication and computation. It is specifically applicable in privacy-sensitive federated solutions whereby, it minimizes the number of information that is exchanged among client-specific devices and central servers, as well, it also renders the user information more secure on an individual basis. "schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} Nevertheless,
 the federated adaptation is only successful in hybrid approach the art of biological continuous updating a
nd amalgamating the already obtained user embeddings. They are commonly constructed when the information th
at is being used is an inhomogeneous set of users, and when exploited irresponsibly can be known to produce
 misguided suggestions, or even cause a performance decline because behaviour or interests of a user in var
ious aspects are not matched. To mitigate such risks, new federated systems are based on high parameter-eff
icient ahead of time tuning, including adapter-based tuning and prompt-based tuning. In this specific insta
nce, these special techniques are designed to only scale the smaller percentage of parameter model (e.g. li
ghtweight adapters, or prompt vectors), and thus cause an enormous decrease in both the costs of communicat
ion and computation. It is specifically applicable in privacy-sensitive federated solutions whereby, it min
imizes the number of information that is exchanged among client-specific devices and central servers, as we
ll, it also renders the user information more secure on an individual basis. (Carreira-Perpiñán, 2017; Y. C

"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} Nevertheless, the federated adaptation is only successful in hybrid approach the art of biological continuous updating and amalgamating the already obtained user embeddings. They are commonly constructed when the information that is being used is an inhomogeneous set of users, and when exploited irresponsibly can be known to produce misguided suggestions, or even cause a performance decline because behaviour or interests of a user in various aspects are not matched. To mitigate such risks, new federated systems are based on high parameter-efficient ahead of time tuning, including adapter-based tuning and prompt-based tuning. In this specific instance, these special techniques are designed to only scale the smaller percentage of parameter model (e.g. lightweight adapters, or prompt vectors), and thus cause an enormous decrease in both the costs of communication and computation. It is specifically applicable in privacy-sensitive federated solutions whereby, it minimizes the number of information that is exchanged among client-specific devices and central servers, as well, it also renders the user information more secure on an individual basis. "schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} Nevertheless,
 the federated adaptation is only successful in hybrid approach the art of biological continuous updating a
nd amalgamating the already obtained user embeddings. They are commonly constructed when the information th
at is being used is an inhomogeneous set of users, and when exploited irresponsibly can be known to produce
 misguided suggestions, or even cause a performance decline because behaviour or interests of a user in var
ious aspects are not matched. To mitigate such risks, new federated systems are based on high parameter-eff
icient ahead of time tuning, including adapter-based tuning and prompt-based tuning. In this specific insta
nce, these special techniques are designed to only scale the smaller percentage of parameter model (e.g. li
ghtweight adapters, or prompt vectors), and thus cause an enormous decrease in both the costs of communicat

ion and computation. It is specifically applicable in privacy-sensitive federated solutions whereby, it min
imizes the number of information that is exchanged among client-specific devices and central servers, as we
ll, it also renders the user information more secure on an individual basis. (Carreira-Perpiñán, 2017; Y. C

"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} Nevertheless,
 the federated adaptation is only successful in hybrid approach the art of biological continuous updating a
nd amalgamating the already obtained user embeddings. They are commonly constructed when the information th
at is being used is an inhomogeneous set of users, and when exploited irresponsibly can be known to produce
 misguided suggestions, or even cause a performance decline because behaviour or interests of a user in var
ious aspects are not matched. To mitigate such risks, new federated systems are based on high parameter-eff
icient ahead of time tuning, including adapter-based tuning and prompt-based tuning. In this specific insta
nce, these special techniques are designed to only scale the smaller percentage of parameter model (e.g. li
ghtweight adapters, or prompt vectors), and thus cause an enormous decrease in both the costs of communicat
ion and computation. It is specifically applicable in privacy-sensitive federated solutions whereby, it min
imizes the number of information that is exchanged among client-specific devices and central servers, as we
ll, it also renders the user information more secure on an individual basis. (Carreira-Perpiñán, 2017; Y. C

"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} Nevertheless,
 the federated adaptation is only successful in hybrid approach the art of biological continuous updating a
nd amalgamating the already obtained user embeddings. They are commonly constructed when the information th
at is being used is an inhomogeneous set of users, and when exploited irresponsibly can be known to produce
 misguided suggestions, or even cause a performance decline because behaviour or interests of a user in var
ious aspects are not matched. To mitigate such risks, new federated systems are based on high parameter-eff
icient ahead of time tuning, including adapter-based tuning and prompt-based tuning. In this specific insta
nce, these special techniques are designed to only scale the smaller percentage of parameter model (e.g. li
ghtweight adapters, or prompt vectors), and thus cause an enormous decrease in both the costs of communicat
ion and computation. It is specifically applicable in privacy-sensitive federated solutions whereby, it min
imizes the number of information that is exchanged among client-specific devices and central servers, as we
ll, it also renders the user information more secure on an individual basis. (Carreira-Perpiñán, 2017; Y. C

at is being used is an inhomogeneous set of users, and when exploited irresponsibly can be known to produce
 misguided suggestions, or even cause a performance decline because behaviour or interests of a user in var
ious aspects are not matched. To mitigate such risks, new federated systems are based on high parameter-eff
icient ahead of time tuning, including adapter-based tuning and prompt-based tuning. In this specific insta
nce, these special techniques are designed to only scale the smaller percentage of parameter model (e.g. li
ghtweight adapters, or prompt vectors), and thus cause an enormous decrease in both the costs of communicat
ion and computation. It is specifically applicable in privacy-sensitive federated solutions whereby, it min
imizes the number of information that is exchanged among client-specific devices and central servers, as we
ll, it also renders the user information more secure on an individual basis. (Carreira-Perpiñán, 2017; Y. C

They are commonly constructed when the information that is being used is an inhomogeneous set of users, and when exploited irresponsibly can be known to produce misguided suggestions, or even cause a performance decline because behaviour or interests of a user in various aspects are not matched. To mitigate such risks, new federated systems are based on high parameter-efficient ahead of time tuning, including adapter-based tuning and prompt-based tuning. In this specific instance, these special techniques are designed to only scale the smaller percentage of parameter model (e.g. lightweight adapters, or prompt vectors), and thus cause an enormous decrease in both the costs of communication and computation. It is specifically applicable in privacy-sensitive federated solutions whereby, it minimizes the number of information that is exchanged among client-specific devices and central servers, as well, it also renders the user information more secure on an individual basis. They are commonly constructed when the information that is being used is an inhomogeneous set of users, and when exploited irresponsibly can be known to produce misguided suggestions, or even cause a performance decline because behaviour or interests of a user in various aspects are not matched. To mitigate such risks, new federated systems are based on high parameter-efficient ahead of time tuning, including adapter-based tuning and prompt-based tuning. In this specific instance, these special techniques are designed to only scale the smaller percentage of parameter model (e.g. lightweight adapters, or prompt vectors), and thus cause an enormous decrease in both the costs of communication and computation. It is specifically applicable in privacy-sensitive federated solutions whereby, it minimizes the number of information that is exchanged among client-specific devices and central servers, as well, it also renders the user information more secure on an individual basis. "schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} Nevertheless,
 the federated adaptation is only successful in hybrid approach the art of biological continuous updating a
nd amalgamating the already obtained user embeddings. They are commonly constructed when the information th
at is being used is an inhomogeneous set of users, and when exploited irresponsibly can be known to produce
 misguided suggestions, or even cause a performance decline because behaviour or interests of a user in var
ious aspects are not matched. To mitigate such risks, new federated systems are based on high parameter-eff
icient ahead of time tuning, including adapter-based tuning and prompt-based tuning. In this specific insta
nce, these special techniques are designed to only scale the smaller percentage of parameter model (e.g. li
ghtweight adapters, or prompt vectors), and thus cause an enormous decrease in both the costs of communicat
ion and computation. It is specifically applicable in privacy-sensitive federated solutions whereby, it min
imizes the number of information that is exchanged among client-specific devices and central servers, as we
ll, it also renders the user information more secure on an individual basis. (Carreira-Perpiñán, 2017; Y. C

Traditional machine learning (ML) as well as deep learning (DL) approaches for heart disease detection often rely on centralized data, which raises concerns about data privacy, security, and accessibility. Recently, Federated Learning (FL), a decentralized machine learning paradigm, has emerged as a promising solution to these challenges. This paper explores the application of Deep Federated Learning (DFL) algorithms in the detection of heart disease namely Federated Averaging (FedAvg), Federated Learning with Differential Privacy (DP-FL), Federated Transfer Learning (FTL), Personalized FL (PFL) and Lightweight FL (LFL).We also discuss the principles of FL, its integration with deep learning models, and its advantages in healthcare specially for heart diseases detection. Additionally, we review recent advancements, challenges, and future directions in this field. Finally, it is observed that Personalized Federated Learning (PFL) achieves the highest performance with 96.2% accuracy, 96.4% F1-score that demonstrating the benefits of adapting models to individual client data.\",\"container-title\":\"Journal of Information Systems Engineering and Management\",\"DOI\":\"10.52783/jisem.v10i25s.4035\",\"issue\":\"25s\",\"journalAbbreviation\":\"Journal of Information Systems Engineering and Management\",\"page\":\"399-408\",\"title\":\"Detection of Heart Disease Using Deep Federated Learning Algorithms\",\"volume\":\"10\",\"author\":[{\"family\":\"Kshirod Sarmah\",\"given\":\"None\"}],\"issued\":{\"date-parts\":[[\"2025\"]]}}},{\"id\":916,\"uris\":[\"http://zotero.org/users/local/M0u71wYg/items/8DFG74BQ\"],\"itemData\":{\"id\":916,\"type\":\"article-journal\",\"abstract\":\"Federated learning (FL), which enables collaborative learning across distributed nodes, confronts a significant heterogeneity challenge, primarily including resource heterogeneity induced by different hardware platforms, and statistical heterogeneity originating from non-IID private data distributions among clients. Neural architecture search (NAS), particularly one-shot NAS, holds great promise for automatically designing optimal personalized models tailored to such heterogeneous scenarios. However, the coexistence of both resource and statistical heterogeneity destabilizes the training of the one-shot supernet, impairs the evaluation of candidate architectures, and ultimately hinders the discovery of optimal personalized models. To address this problem, we propose a heterogeneity-aware personalized federated NAS (HAPFNAS) method. First, we leverage lightweight knowledge models to distill knowledge from clients to server-side supernet, thereby effectively mitigating the effects of heterogeneity and enhancing the training stability. Then, we build random-forest-based personalized performance predictors to enable the efficient evaluation of candidate architectures across clients. Furthermore, we develop a model-heterogeneous FL algorithm called heteroFedAvg to facilitate collaborative model training for the discovered personalized models. Comprehensive experiments on CIFAR-10/100 and Tiny-ImageNet classification datasets demonstrate the effectiveness of our HAPFNAS, compared to state-of-the-art federated NAS methods.\",\"container-title\":\"Entropy\",\"DOI\":\"10.3390/e27070759\",\"issue\":\"7\",\"journalAbbreviation\":\"Entropy\",\"page\":\"759\",\"title\":\"Heterogeneity-Aware Personalized Federated Neural Architecture Search\",\"volume\":\"27\",\"author\":[{\"family\":\"Yang\",\"given\":\"An\"},{\"family\":\"Liu\",\"given\":\"Ying\"}],\"issued\":{\"date-parts\":[[\"2025\"]]}}},{\"id\":914,\"uris\":[\"http://zotero.org/users/local/M0u71wYg/items/CLI96AAH\"],\"itemData\":{\"id\":914,\"type\":\"article-journal\",\"abstract\":\"Lightweight training and distributed tiny data storage in local model will lead to the severe challenge of convergence for tiny federated learning (FL). Achieving fast convergence in tiny FL is crucial for many emerging applications in Internet of Unmanned Aerial Vehicles (IUAVs) networks. Excessive information exchange between UAVs and IoT devices could lead to security risks and data breaches, while insufficient information can slow down the learning process and negatively system performance experience due to significant computational and communication constraints in tiny FL hardware system. This paper proposes a trusting, low latency, and energy-efficient tiny wireless FL framework with blockchain (TBWFL) for IUAV systems. We develop a quantifiable model to determine the trustworthiness of IoT devices in IUAV networks. This model incorporates the time spent in communication, computation, and block production with a decay function in each round of FL at the UAVs. Then it combines the trust information from different UAVs, considering their credibility of trust recommendation. We formulate the TBWFL as an optimization problem that balances trustworthiness, learning speed, and energy consumption for IoT devices with diverse computing and energy capabilities. We decompose the complex optimization problem into three sub-problems for improved local accuracy, fast learning, trust verification, and energy efficiency of IoT devices. Our extensive experiments show that TBWFL offers higher trustworthiness, faster convergence, and lower energy consumption than the existing state-of-the-art FL scheme.\",\"container-title\":\"IEEE Internet of Things Journal\",\"DOI\":\"10.1109/jiot.2024.3363443\",\"issue\":\"12\",\"journalAbbreviation\":\"IEEE Internet of Things Journal\",\"page\":\"21046-21060\",\"title\":\"Trust Management of Tiny Federated Learning in Internet of Unmanned Aerial Vehicles\",\"volume\":\"11\",\"author\":[{\"family\":\"Zheng\",\"given\":\"Jie\"},{\"family\":\"Xu\",\"given\":\"Jipeng\"},{\"family\":\"Du\",\"given\":\"Hongyang\"},{\"family\":\"Niyato\",\"given\":\"Dusit\"},{\"family\":\"Kang\",\"given\":\"Jiawen\"},{\"family\":\"Nie\",\"given\":\"Jiangtian\"},{\"family\":\"Wang\",\"given\":\"Zheng\"}],\"issued\":{\"date-parts\":[[\"2024\"]]}}}],\"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} On another attempt to achieve the balance between the foundation models strength and the practicability of mobile federated learning is a trend of development of more and more personalised adapters. They are tiny modules which ought to have the capability of learning and encoding preferences in individual users without putting much strain on the computing and memory. The customisation adapters allow offering finer-grained and adaptive suggestion services to trade-offs between mixed and universal knowledge and consider the presence of user-specific personalisation. Better still, they do so without invading the privacy of the users either as sensitive information about individual aspects of behaviour is not sent anywhere because it is stored in one of the local storage of the user to the device itself and is never transmitted to the servers out there. Besides this, further research on federated prompt tuning and continuous learning in these models can also be an efficient direction, to make them more personal and offer context-sensitivity, by allowing them to spend more computational power on optimizing the models with new information generated privately. More specific attention needs to be paid to the architectural design and privacy mechanisms of the said federated recommender systems since they are the most important elements to influence the say-off between the accuracy of the recommendation model and privacy of user information. This incorporates a subtle understanding of the dissimilarly secretive protocol and secure summation algorithms which can effortlessly blend so as to result in the forecasting capability of elevated foundation models being eroded to an unreasonable scope. Thus a subsequent study should be aimed at optimization of these privacy enhancing technologies such that it can be in a position to ensure high recommendability, as much as can be, and absolute safety of the sensitive information knowledge of the user with the distributed learning paradigm. This optimisation refers to the search of other ways to compress gradient and asynchronous updating protocols that can bring the cost of communication and ability to cover heterogeneity of clients to a bearable threshold, and will be fundamental in the future expansion of federated learning to large user bases and multifaceted foundation architecture. In addition, the adaptive regularization policies and the client-adapted federated learning algorithms also can be examined to enhance the performance further in the model and alleviate client drift in conditions where the data distribution is highly non-IID, which is characteristic to mobile feedback recommendation under realistic settings. Moreover, with the ability to optimize the resources by tuning the fine details of the resource based devices, several methods like heterogeneous Low-Rank Adaptation will arrive at the optimal solution of operation only by consuming the minimum communication resources without overfitting simultaneously. Besides this, further research on federated prompt tuning and continuous learning in these models can also be an efficient direction, to make them more personal and offer context-sensitivity, by allowing them to spend more computational power on optimizing the models with new information generated privately. More specific attention needs to be paid to the architectural design and privacy mechanisms of the said federated recommender systems since they are the most important elements to influence the say-off between the accuracy of the recommendation model and privacy of user information. This incorporates a subtle understanding of the dissimilarly secretive protocol and secure summation algorithms which can effortlessly blend so as to result in the forecasting capability of elevated foundation models being eroded to an unreasonable scope. Thus a subsequent study should be aimed at optimization of these privacy enhancing technologies such that it can be in a position to ensure high recommendability, as much as can be, and absolute safety of the sensitive information knowledge of the user with the distributed learning paradigm. This optimisation refers to the search of other ways to compress gradient and asynchronous updating protocols that can bring the cost of communication and ability to cover heterogeneity of clients to a bearable threshold, and will be fundamental in the future expansion of federated learning to large user bases and multifaceted foundation architecture. In addition, the adaptive regularization policies and the client-adapted federated learning algorithms also can be examined to enhance the performance further in the model and alleviate client drift in conditions where the data distribution is highly non-IID, which is characteristic to mobile feedback recommendation under realistic settings. eover, with the ability to optimize the resources by tuning the fine details of the resource based devices,
 several methods like heterogeneous Low-Rank Adaptation will arrive at the optimal solution of operation on
ly by consuming the minimum communication resources without overfitting simultaneously. Besides this, furth
er research on federated prompt tuning and continuous learning in these models can also be an efficient dir
ection, to make them more personal and offer context-sensitivity, by allowing them to spend more computatio
nal power on optimizing the models with new information generated privately. More specific attention needs
to be paid to the architectural design and privacy mechanisms of the said federated recommender systems sin
ce they are the most important elements to influence the say-off between the accuracy of the recommendation
 model and privacy of user information. This incorporates a subtle understanding of the dissimilarly secret
ive protocol and secure summation algorithms which can effortlessly blend so as to result in the forecastin
g capability of elevated foundation models being eroded to an unreasonable scope. Thus a subsequent study s
hould be aimed at optimization of these privacy enhancing technologies such that it can be in a position to
 ensure high recommendability, as much as can be, and absolute safety of the sensitive information knowledg
e of the user with the distributed learning paradigm. This optimisation refers to the search of other ways
to compress gradient and asynchronous updating protocols that can bring the cost of communication and abili
ty to cover heterogeneity of clients to a bearable threshold, and will be fundamental in the future expansi
on of federated learning to large user bases and multifaceted foundation architecture. In addition, the ada
ptive regularization policies and the client-adapted federated learning algorithms also can be examined to
enhance the performance further in the model and alleviate client drift in conditions where the data distri
bution is highly non-IID, which is characteristic to mobile feedback recommendation under realistic setting

\"]]}}}],\"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} Moreover, with the ability to optimize the resources by tuning the fine details of the resource based devices, several methods like heterogeneous Low-Rank Adaptation will arrive at the optimal solution of operation only by consuming the minimum communication resources without overfitting simultaneously. Besides this, furth

er research on federated prompt tuning and continuous learning in these models can also be an efficient direction, to make them more personal and offer context-sensitivity, by allowing them to spend more computational power on optimizing the models with new information generated privately. More specific attention needs to be paid to the architectural design and privacy mechanisms of the said federated recommender systems since they are the most important elements to influence the say-off between the accuracy of the recommendation model and privacy of user information. This incorporates a subtle understanding of the dissimilarly secretive protocol and secure summation algorithms which can effortlessly blend so as to result in the forecasting capability of elevated foundation models being eroded to an unreasonable scope. Thus a subsequent study should be aimed at optimization of these privacy enhancing technologies such that it can be in a position to ensure high recommendability, as much as can be, and absolute safety of the sensitive information knowledge of the user with the distributed learning paradigm. This optimisation refers to the search of other ways to compress gradient and asynchronous updating protocols that can bring the cost of communication and ability to cover heterogeneity of clients to a bearable threshold, and will be fundamental in the future expansion of federated learning to large user bases and multifaceted foundation architecture. In addition, the adaptive regularization policies and the client-adapted federated learning algorithms also can be examined to enhance the performance further in the model and alleviate client drift in conditions where the data distribution is highly non-IID, which is characteristic to mobile feedback recommendation under realistic settings. eover, with the ability to optimize the resources by tuning the fine details of the resource based devices,
 several methods like heterogeneous Low-Rank Adaptation will arrive at the optimal solution of operation on
ly by consuming the minimum communication resources without overfitting simultaneously. Besides this, furth
er research on federated prompt tuning and continuous learning in these models can also be an efficient dir
ection, to make them more personal and offer context-sensitivity, by allowing them to spend more computatio
nal power on optimizing the models with new information generated privately. More specific attention needs
to be paid to the architectural design and privacy mechanisms of the said federated recommender systems sin
ce they are the most important elements to influence the say-off between the accuracy of the recommendation
 model and privacy of user information. This incorporates a subtle understanding of the dissimilarly secret
ive protocol and secure summation algorithms which can effortlessly blend so as to result in the forecastin
g capability of elevated foundation models being eroded to an unreasonable scope. Thus a subsequent study s
hould be aimed at optimization of these privacy enhancing technologies such that it can be in a position to
 ensure high recommendability, as much as can be, and absolute safety of the sensitive information knowledg
e of the user with the distributed learning paradigm. This optimisation refers to the search of other ways
to compress gradient and asynchronous updating protocols that can bring the cost of communication and abili
ty to cover heterogeneity of clients to a bearable threshold, and will be fundamental in the future expansi
on of federated learning to large user bases and multifaceted foundation architecture. In addition, the ada
ptive regularization policies and the client-adapted federated learning algorithms also can be examined to
enhance the performance further in the model and alleviate client drift in conditions where the data distri
bution is highly non-IID, which is characteristic to mobile feedback recommendation under realistic setting

Besides this, further research on federated prompt tuning and continuous learning in these models can also be an efficient direction, to make them more personal and offer context-sensitivity, by allowing them to spend more computational power on optimizing the models with new information generated privately. More specific attention needs to be paid to the architectural design and privacy mechanisms of the said federated recommender systems since they are the most important elements to influence the say-off between the accuracy of the recommendation model and privacy of user information. This incorporates a subtle understanding of the dissimilarly secretive protocol and secure summation algorithms which can effortlessly blend so as to result in the forecasting capability of elevated foundation models being eroded to an unreasonable scope. Thus a subsequent study should be aimed at optimization of these privacy enhancing technologies such that it can be in a position to ensure high recommendability, as much as can be, and absolute safety of the sensitive information knowledge of the user with the distributed learning paradigm. This optimisation refers to the search of other ways to compress gradient and asynchronous updating protocols that can bring the cost of communication and ability to cover heterogeneity of clients to a bearable threshold, and will be fundamental in the future expansion of federated learning to large user bases and multifaceted foundation architecture. In addition, the adaptive regularization policies and the client-adapted federated learning algorithms also can be examined to enhance the performance further in the model and alleviate client drift in conditions where the data distribution is highly non-IID, which is characteristic to mobile feedback recommendation under realistic settings. Irrespective of these changes, it remains evident that there are still some harsh hardware and algorithmic constraints that must be overcome. Trade-off This trade-off is typically accomplished via efficiency constraints, particularly when placed on model complexity-reduction, which certainly might affect the training rate and the overall machine efficiency. Overcoming these challenges, new model architectures tailored to federated environment would be necessary the architectures that incur minimum communication costs and minimum computational requirements on single devices, and which are very predictable. (H. Fan et al., 2023; Ha et al., 2025; S. Han et al., 2024; L. Li et al., 2025b; Y. Liu et al., 2023b; K. Peng et al., 2023; Tong et al., 2025; H.-Y. Tran et al., 2023; W. Yao et al., 2025)",

Meanwhile, the cross-device federated learning structure will unlock the bottlenecks of calculating and transferring data that, specifically, on the basis of massive foundation models will demand the new mechanisms of resource management and offloading of tasks. These techniques play a very important role in the trade-off between cost of communication, and the cost of computation locally, which turns crucial in the instance of fine-tuning at scale of large models when prediction is required to predict applications such as movie recommender. To address these issues, we need to develop lean and mobile optimised versions of neural networks, which can successfully be implemented on portable devices, and which can attract fewer energy, and less resources. Further reduction of the model footprint and the computing needs could also be accomplished by pruning and adaptive quantisation - federated learning can be made available even on a broader range of mobile devices. It is also hectic that engineers and designers face in the implementation of the foundation models of these such systems especially the real-time performance and scalability in the industrial applications. The computation amounts to and communication efficiency maximisation in federated learning systems, in more detail of complex multi-modal models such as GPT-4o is an excellent problem, and often involves distributed strategies of computation to manage the colossal resource consumption, intrinsic in training and fine-tuning such models over time with massive compute clusters. ge/schema/raw/master/csl-citation.json\"} Higher security and fault tolerance: Decentralised federated lear
ning is a peer-to-peer communication framework that can be enhanced with regard to superior security and fa
ult tolerance. Meanwhile, the cross-device federated learning structure will unlock the bottlenecks of calc
ulating and transferring data that, specifically, on the basis of massive foundation models will demand the
 new mechanisms of resource management and offloading of tasks. These techniques play a very important role
 in the trade-off between cost of communication, and the cost of computation locally, which turns crucial i
n the instance of fine-tuning at scale of large models when prediction is required to predict applications
such as movie recommender. To address these issues, we need to develop lean and mobile optimised versions o
f neural networks, which can successfully be implemented on portable devices, and which can attract fewer e
nergy, and less resources. Further reduction of the model footprint and the computing needs could also be a
ccomplished by pruning and adaptive quantisation - federated learning can be made available even on a broad
er range of mobile devices. It is also hectic that engineers and designers face in the implementation of th
e foundation models of these such systems especially the real-time performance and scalability in the indus
trial applications. The computation amounts to and communication efficiency maximisation in federated learn
ing systems, in more detail of complex multi-modal models such as GPT-4o is an excellent problem, and often
 involves distributed strategies of computation to manage the colossal resource consumption, intrinsic in t
raining and fine-tuning such models over time with massive compute clusters. (Abbaszadi, 2025; Akon et al.,

Higher security and fault tolerance: Decentralised federated learning is a peer-to-peer communication framework that can be enhanced with regard to superior security and fault tolerance. Meanwhile, the cross-device federated learning structure will unlock the bottlenecks of calculating and transferring data that, specifically, on the basis of massive foundation models will demand the new mechanisms of resource management and offloading of tasks. These techniques play a very important role in the trade-off between cost of communication, and the cost of computation locally, which turns crucial in the instance of fine-tuning at scale of large models when prediction is required to predict applications such as movie recommender. To address these issues, we need to develop lean and mobile optimised versions of neural networks, which can successfully be implemented on portable devices, and which can attract fewer energy, and less resources. Further reduction of the model footprint and the computing needs could also be accomplished by pruning and adaptive quantisation - federated learning can be made available even on a broader range of mobile devices. It is also hectic that engineers and designers face in the implementation of the foundation models of these such systems especially the real-time performance and scalability in the industrial applications. The computation amounts to and communication efficiency maximisation in federated learning systems, in more detail of complex multi-modal models such as GPT-4o is an excellent problem, and often

```
 involves distributed strategies of computation to manage the colossal resource consumption, intrinsic in t
raining and fine-tuning such models over time with massive compute clusters. (Abbaszadi, 2025; Akon et al.,

:\"Musleh\"},{\"family\":\"Khan\",\"given\":\"Muhammad Amir\"},{\"family\":\"Alsadie\",\"given\":\"Deafallah\"},{\"family\":\"Jilani Saudagar\",\"given\":\"Abdul Khader\"},{\"family\":\"Alkhathami\",\"given\":\"Mohammed\"}],\"issued\":{\"date-parts\":[[\"2023\"]]}}}],\"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} Higher security and fault tolerance: Decentralised federated learning is a peer-to-peer communication framework that can be enhanced with regard to superior security and fault tolerance. Meanwhile, the cross-device federated learning structure will unlock the bottlenecks of calculating and transferring data that, specifically, on the basis of massive foundation models will demand the new mechanisms of resource management and offloading of tasks. These techniques play a very important role in the trade-off between cost of communication, and the cost of computation locally, which turns crucial in the instance of fine-tuning at scale of large models when prediction is required to predict applications such as movie recommender. To address these issues, we need to develop lean and mobile optimised versions of neural networks, which can successfully be implemented on portable devices, and which can attract fewer energy, and less resources. Further reduction of the model footprint and the computing needs could also be accomplished by pruning and adaptive quantisation - federated learning can be made available even on a broader range of mobile devices. It is also hectic that engineers and designers face in the implementation of the foundation models of these such systems especially the real-time performance and scalability in the industrial applications. The computation amounts to and communication efficiency maximisation in federated learning systems, in more detail of complex multi-modal models such as GPT-4o is an excellent problem, and often involves distributed strategies of computation to manage the colossal resource consumption, intrinsic in training and fine-tuning such models over time with massive compute clusters. ge/schema/raw/master/csl-citation.json\"} Higher security and fault tolerance: Decentralised federated lear
ning is a peer-to-peer communication framework that can be enhanced with regard to superior security and fa
ult tolerance. Meanwhile, the cross-device federated learning structure will unlock the bottlenecks of calc
ulating and transferring data that, specifically, on the basis of massive foundation models will demand the
 new mechanisms of resource management and offloading of tasks. These techniques play a very important role
 in the trade-off between cost of communication, and the cost of computation locally, which turns crucial i
n the instance of fine-tuning at scale of large models when prediction is required to predict applications 
such as movie recommender. To address these issues, we need to develop lean and mobile optimised versions o
f neural networks, which can successfully be implemented on portable devices, and which can attract fewer e
nergy, and less resources. Further reduction of the model footprint and the computing needs could also be a
ccomplished by pruning and adaptive quantisation - federated learning can be made available even on a broad
er range of mobile devices. It is also hectic that engineers and designers face in the implementation of th
e foundation models of these such systems especially the real-time performance and scalability in the indus
trial applications. The computation amounts to and communication efficiency maximisation in federated learn
ing systems, in more detail of complex multi-modal models such as GPT-4o is an excellent problem, and often
 involves distributed strategies of computation to manage the colossal resource consumption, intrinsic in t
raining and fine-tuning such models over time with massive compute clusters. (Abbaszadi, 2025; Akon et al.,

Meanwhile, the cross-device federated learning structure will unlock the bottlenecks of calculating and transferring data that, specifically, on the basis of massive foundation models will demand the new mechanisms of resource management and offloading of tasks. These techniques play a very important role in the trade-off between cost of communication, and the cost of computation locally, which turns crucial in the instance of fine-tuning at scale of large models when prediction is required to predict applications such as movie recommender. To address these issues, we need to develop lean and mobile optimised versions of neural networks, which can successfully be implemented on portable devices, and which can attract fewer energy, and less resources. Further reduction of the model footprint and the computing needs could also be accomplished by pruning and adaptive quantisation - federated learning can be made available even on a broader range of mobile devices. It is also hectic that engineers and designers face in the implementation of the foundation models of these such systems especially the real-time performance and scalability in the industrial applications. The computation amounts to and communication efficiency maximisation in federated learning systems, in more detail of complex multi-modal models such as GPT-4o is an excellent problem, and often involves distributed strategies of computation to manage the colossal resource consumption, intrinsic in training and fine-tuning such models over time with massive compute clusters. Higher security and fault tolerance: Decentralised federated learning is a peer-to-peer communication framework that can be enhanced with regard to superior security and fault tolerance. Meanwhile, the cross-device federated learning structure will unlock the bottlenecks of calculating and transferring data that, specifically, on the basis of massive foundation models will demand the new mechanisms of resource management and offloading of tasks. These techniques play a very important role in the trade-off between cost of communication, and the cost of computation locally, which turns crucial in the instance of fine-tuning at scale of large models when prediction is required to predict applications such as movie recommender. To address these issues, we need to develop lean and mobile optimised versions of neural networks, which can successfully be implemented on portable devices, and which can attract fewer energy, and less resources. Further reduction of the model footprint and the computing needs could also be accomplished by pruning and adaptive quantisation - federated learning can be made available even on a broader range of mobile devices. It is also hectic that engineers and designers face in the implementation of the foundation models of these such systems especially the real-time performance and scalability in the industrial applications. The computation amounts to and communication efficiency maximisation in federated learning systems, in more detail of complex multi-modal models such as GPT-4o is an excellent problem, and often involves distributed strategies of computation to manage the colossal resource consumption, intrinsic in training and fine-tuning such models over time with massive compute clusters. Higher security and fault tolerance: Decentralised federated learning is a peer-to-peer communication framework that can be enhanced with regard to superior security and fault tolerance. Meanwhile, the cross-device federated learning structure will unlock the bottlenecks of calculating and transferring data that, specifically, on the basis of massive foundation models will demand the new mechanisms of resource management and offloading of tasks. These techniques play a very important role in the trade-off between cost of communication, and the cost of computation locally, which turns crucial in the instance of fine-tuning at scale of large models when prediction is required to predict applications such as movie recommender. To address these issues, we need to develop lean and mobile optimised versions of neural networks, which can successfully be implemented on portable devices, and which can attract fewer energy, and less resources. Further reduction of the model footprint and the computing needs could also be accomplished by pruning and adaptive quantisation - federated learning can be made available even on a broader range of mobile devices. It is also hectic that engineers and designers face in the implementation of the foundation models of these such systems especially the real-time performance and scalability in the industrial applications. The computation amounts to and communication efficiency maximisation in federated learning systems, in more detail of complex multi-modal models such as GPT-4o is an excellent problem, and often involves distributed strategies of computation to manage the colossal resource consumption, intrinsic in training and fine-tuning such models over time with massive compute clusters. ge/schema/raw/master/csl-citation.json\"} Higher security and fault tolerance: Decentralised federated learning is a peer-to-peer communication framework that can be enhanced with regard to superior security and fault tolerance. Meanwhile, the cross-device federated learning structure will unlock the bottlenecks of calculating and transferring data that, specifically, on the basis of massive foundation models will demand the new mechanisms of resource management and offloading of tasks. These techniques play a very important role in the trade-off between cost of communication, and the cost of computation locally, which turns crucial in the instance of fine-tuning at scale of large models when prediction is required to predict applications

```
such as movie recommender. To address these issues, we need to develop lean and mobile optimised versions o
f neural networks, which can successfully be implemented on portable devices, and which can attract fewer e
nergy, and less resources. Further reduction of the model footprint and the computing needs could also be a
ccomplished by pruning and adaptive quantisation - federated learning can be made available even on a broad
er range of mobile devices. It is also hectic that engineers and designers face in the implementation of th
e foundation models of these such systems especially the real-time performance and scalability in the indus
trial applications. The computation amounts to and communication efficiency maximisation in federated learn
ing systems, in more detail of complex multi-modal models such as GPT-4o is an excellent problem, and often
 involves distributed strategies of computation to manage the colossal resource consumption, intrinsic in t
raining and fine-tuning such models over time with massive compute clusters. (Abbaszadi, 2025; Akon et al.,

ammed\"}],\"issued\":{\"date-parts\":[[\"2023\"]]}}}],\"schema\":\"https://github.com/citation-style-langua
ge/schema/raw/master/csl-citation.json\"} Higher security and fault tolerance: Decentralised federated lear
ning is a peer-to-peer communication framework that can be enhanced with regard to superior security and fa
ult tolerance. Meanwhile, the cross-device federated learning structure will unlock the bottlenecks of calc
ulating and transferring data that, specifically, on the basis of massive foundation models will demand the
 new mechanisms of resource management and offloading of tasks. These techniques play a very important role
 in the trade-off between cost of communication, and the cost of computation locally, which turns crucial i
n the instance of fine-tuning at scale of large models when prediction is required to predict applications 
such as movie recommender. To address these issues, we need to develop lean and mobile optimised versions o
f neural networks, which can successfully be implemented on portable devices, and which can attract fewer e
nergy, and less resources. Further reduction of the model footprint and the computing needs could also be a
ccomplished by pruning and adaptive quantisation - federated learning can be made available even on a broad
er range of mobile devices. It is also hectic that engineers and designers face in the implementation of th
e foundation models of these such systems especially the real-time performance and scalability in the indus
trial applications. The computation amounts to and communication efficiency maximisation in federated learn
ing systems, in more detail of complex multi-modal models such as GPT-4o is an excellent problem, and often
 involves distributed strategies of computation to manage the colossal resource consumption, intrinsic in t
raining and fine-tuning such models over time with massive compute clusters. (Abbaszadi, 2025; Akon et al.,

Higher security and fault tolerance: Decentralised federated learning is a peer-to-peer communication framework that can be enhanced with regard to superior security and fault tolerance. Meanwhile, the cross-device federated learning structure will unlock the bottlenecks of calculating and transferring data that, specifically, on the basis of massive foundation models will demand the new mechanisms of resource management and offloading of tasks. These techniques play a very important role in the trade-off between cost of communication, and the cost of computation locally, which turns crucial in the instance of fine-tuning at scale of large models when prediction is required to predict applications such as movie recommender. To address these issues, we need to develop lean and mobile optimised versions of neural networks, which can successfully be implemented on portable devices, and which can attract fewer energy, and less resources. Further reduction of the model footprint and the computing needs could also be accomplished by pruning and adaptive quantisation - federated learning can be made available even on a broader range of mobile devices. It is also hectic that engineers and designers face in the implementation of the foundation models of these such systems especially the real-time performance and scalability in the industrial applications. The computation amounts to and communication efficiency maximisation in federated learning systems, in more detail of complex multi-modal models such as GPT-4o is an excellent problem, and often involves distributed strategies of computation to manage the colossal resource consumption, intrinsic in training and fine-tuning such models over time with massive compute clusters. ge/schema/raw/master/csl-citation.json\"} Higher security and fault tolerance: Decentralised federated lear
ning is a peer-to-peer communication framework that can be enhanced with regard to superior security and fa
ult tolerance. Meanwhile, the cross-device federated learning structure will unlock the bottlenecks of calc
ulating and transferring data that, specifically, on the basis of massive foundation models will demand the
 new mechanisms of resource management and offloading of tasks. These techniques play a very important role
 in the trade-off between cost of communication, and the cost of computation locally, which turns crucial i
n the instance of fine-tuning at scale of large models when prediction is required to predict applications
such as movie recommender. To address these issues, we need to develop lean and mobile optimised versions o
f neural networks, which can successfully be implemented on portable devices, and which can attract fewer e
nergy, and less resources. Further reduction of the model footprint and the computing needs could also be a
ccomplished by pruning and adaptive quantisation - federated learning can be made available even on a broad
er range of mobile devices. It is also hectic that engineers and designers face in the implementation of th
e foundation models of these such systems especially the real-time performance and scalability in the indus
trial applications. The computation amounts to and communication efficiency maximisation in federated learn
ing systems, in more detail of complex multi-modal models such as GPT-4o is an excellent problem, and often
 involves distributed strategies of computation to manage the colossal resource consumption, intrinsic in t
raining and fine-tuning such models over time with massive compute clusters. (Abbaszadi, 2025; Akon et al.,

/csl-citation.json\"} Personalisation, in the event of federated learning, particularly by the recommender systems, must be done in a manner that will not jeopardize privacy of the users. This is not simply encryption procedure of the data, and aims at sophisticated mechanisms. One of the techniques studied nowadays is called an advanced privacy or secure multiparty computation, to make sure that the data of the user remain secure, not only during the training of the models, but also during inference. Homomorphic encryption and zero-knowledge overwhelming, e.g., are schemes of ensuring that there exist efficient structures of maintaining privacy without exposing the utility of aggregated updates in a model. Providing personalised federated learning methods would allow creating strong and understandable user representations and ensuring that privacy remains the priority. It is especially relevant since it views the issues in relation to sparse data and statistical difference between the various individuals on which it is hard to conclusively ascertain about the finesse of the users in the proper sense. Also, since user preferences may shift with time, there is always the necessity of models changing with of a changing data distribution. What cannot be defined as being thus deemed to fall under the category of “personality leakage” and what can be done to be held to proper measures on the categorizing of becoming less important is one of the greatest problems that remain unresolved fully, yet (sec. 4). So, it is extremely important to develop improved objective functions and optimisation of strategies with the stated goal of preserving personality during the federation of foundation models refinement. It is also vital to generate mechanisms of the adequate quantification of such trade-offs between the accuracy of personalisation, and the risk of leakage of personality, especially of multidimensional and intricate representations of a consumer. Another issue that is of the particular importance is that advanced models will extract sensitive user traits like personality off of seemingly innocent user-interactions and that is the ethical issue of the misuse of the data and bias of algorithms. To meet these considerations, it is necessary that there exist mechanisms that allow transparent auditing, personal governance such that inferred user features are treated in an irresponsible manner. Moreover, federated foundation models would have to overcome current distribution jumps to achieve an ongoing execution, as traditional risks might lack the ability to address distribution changes, as it must being able to educate all of the parameters and is delicate to variations in the user information. /csl-citation.json\"} Personalisation, in the event of federated learning, particularly by the recommender
systems, must be done in a manner that will not jeopardize privacy of the users. This is not simply encrypt
ion procedure of the data, and aims at sophisticated mechanisms. One of the techniques studied nowadays is
called an advanced privacy or secure multiparty computation, to make sure that the data of the user remain
secure, not only during the training of the models, but also during inference. Homomorphic encryption and z
ero-knowledge overwhelming, e.g., are schemes of ensuring that there exist efficient structures of maintain
ing privacy without exposing the utility of aggregated updates in a model. Providing personalised federated
 learning methods would allow creating strong and understandable user representations and ensuring that pri
vacy remains the priority. It is especially relevant since it views the issues in relation to sparse data a

nd statistical difference between the various individuals on which it is hard to conclusively ascertain abo
ut the finesse of the users in the proper sense. Also, since user preferences may shift with time, there is
 always the necessity of models changing with of a changing data distribution. What cannot be defined as be
ing thus deemed to fall under the category of “personality leakage” and what can be done to be held to prop
er measures on the categorizing of becoming less important is one of the greatest problems that remain unre
solved fully, yet (sec. 4). So, it is extremely important to develop improved objective functions and optim
isation of strategies with the stated goal of preserving personality during the federation of foundation mo
dels refinement. It is also vital to generate mechanisms of the adequate quantification of such trade-offs
between the accuracy of personalisation, and the risk of leakage of personality, especially of multidimensi
onal and intricate representations of a consumer. Another issue that is of the particular importance is tha
t advanced models will extract sensitive user traits like personality off of seemingly innocent user-intera
ctions and that is the ethical issue of the misuse of the data and bias of algorithms. To meet these consid
erations, it is necessary that there exist mechanisms that allow transparent auditing, personal governance
such that inferred user features are treated in an irresponsible manner. Moreover, federated foundation mod
els would have to overcome current distribution jumps to achieve an ongoing execution, as traditional risks
 might lack the ability to address distribution changes, as it must being able to educate all of the parame
ters and is delicate to variations in the user information. (Z. Guo et al., 2024; Priyadarsini \u0026 Raja,

/csl-citation.json\"} Personalisation, in the event of federated learning, particularly by the recommender
systems, must be done in a manner that will not jeopardize privacy of the users. This is not simply encrypt
ion procedure of the data, and aims at sophisticated mechanisms. One of the techniques studied nowadays is
called an advanced privacy or secure multiparty computation, to make sure that the data of the user remain
secure, not only during the training of the models, but also during inference. Homomorphic encryption and z
ero-knowledge overwhelming, e.g., are schemes of ensuring that there exist efficient structures of maintain
ing privacy without exposing the utility of aggregated updates in a model. Providing personalised federated
 learning methods would allow creating strong and understandable user representations and ensuring that pri
vacy remains the priority. It is especially relevant since it views the issues in relation to sparse data a
nd statistical difference between the various individuals on which it is hard to conclusively ascertain abo
ut the finesse of the users in the proper sense. Also, since user preferences may shift with time, there is
 always the necessity of models changing with of a changing data distribution. What cannot be defined as be
ing thus deemed to fall under the category of “personality leakage” and what can be done to be held to prop
er measures on the categorizing of becoming less important is one of the greatest problems that remain unre
solved fully, yet (sec. 4). So, it is extremely important to develop improved objective functions and optim
isation of strategies with the stated goal of preserving personality during the federation of foundation mo
dels refinement. It is also vital to generate mechanisms of the adequate quantification of such trade-offs
 between the accuracy of personalisation, and the risk of leakage of personality, especially of multidimensi
onal and intricate representations of a consumer. Another issue that is of the particular importance is tha
t advanced models will extract sensitive user traits like personality off of seemingly innocent user-intera
ctions and that is the ethical issue of the misuse of the data and bias of algorithms. To meet these consid
erations, it is necessary that there exist mechanisms that allow transparent auditing, personal governance
 such that inferred user features are treated in an irresponsible manner. Moreover, federated foundation mod
els would have to overcome current distribution jumps to achieve an ongoing execution, as traditional risks
 might lack the ability to address distribution changes, as it must being able to educate all of the parame
ters and is delicate to variations in the user information. (Z. Guo et al., 2024; Priyadarsini \u0026 Raja,

systems, must be done in a manner that will not jeopardize privacy of the users. This is not simply encrypt
ion procedure of the data, and aims at sophisticated mechanisms. One of the techniques studied nowadays is
called an advanced privacy or secure multiparty computation, to make sure that the data of the user remain
secure, not only during the training of the models, but also during inference. Homomorphic encryption and z
ero-knowledge overwhelming, e.g., are schemes of ensuring that there exist efficient structures of maintain
ing privacy without exposing the utility of aggregated updates in a model. Providing personalised federated
 learning methods would allow creating strong and understandable user representations and ensuring that pri
vacy remains the priority. It is especially relevant since it views the issues in relation to sparse data a
nd statistical difference between the various individuals on which it is hard to conclusively ascertain abo
ut the finesse of the users in the proper sense. Also, since user preferences may shift with time, there is
 always the necessity of models changing with of a changing data distribution. What cannot be defined as be
ing thus deemed to fall under the category of “personality leakage” and what can be done to be held to prop
er measures on the categorizing of becoming less important is one of the greatest problems that remain unre
solved fully, yet (sec. 4). So, it is extremely important to develop improved objective functions and optim
isation of strategies with the stated goal of preserving personality during the federation of foundation mo
dels refinement. It is also vital to generate mechanisms of the adequate quantification of such trade-offs
between the accuracy of personalisation, and the risk of leakage of personality, especially of multidimensi
onal and intricate representations of a consumer. Another issue that is of the particular importance is tha
t advanced models will extract sensitive user traits like personality off of seemingly innocent user-intera
ctions and that is the ethical issue of the misuse of the data and bias of algorithms. To meet these consid
erations, it is necessary that there exist mechanisms that allow transparent auditing, personal governance
such that inferred user features are treated in an irresponsible manner. Moreover, federated foundation mod
els would have to overcome current distribution jumps to achieve an ongoing execution, as traditional risks
 might lack the ability to address distribution changes, as it must being able to educate all of the parame
ters and is delicate to variations in the user information. (Z. Guo et al., 2024; Priyadarsini \u0026 Raja,

These innovations are also needed to make certain that federated learning systems that act as recommendation engines are adaptive to evolving user requirements, not simply, but also engaged in averting rendering sensitive personality characteristics to whic

h exposing sensitive personality characteristics have increasingly been of a growing concern as foundation models have become increasingly prolific. It is a multi-layered and dynamic issue, and interdisciplinary solutions that encompass advances in machine learning, cyber security and responsible AI are necessary to develop certified and compliant systems that are ready to adapt to new regulations. These innovations are also needed to make certain that federated learning systems that act as recommendation engines are adaptive to evolving user requirements, not simply, but also engaged in averting rendering sensitive personality characteristics to which exposing sensitive personality characteristics have increasingly been of a growing concern as foundation models have become increasingly prolific. It is a multi-layered and dynamic issue, and interdisciplinary solutions that encompass advances in machine learning, cyber security and responsible AI are necessary to develop certified and compliant systems that are ready to adapt to new regulations. These innovations are also needed to make certain that federated learning systems that act as recommendation engines are adaptive to evolving user requirements, not simply, but also engaged in averting rendering sensitive personality characteristics to which exposing sensitive personality characteristics have increasingly been of a growing concern as foundation models have become increasingly prolific. It is a multi-layered and dynamic issue, and interdisciplinary solutions that encompass advances in machine learning, cyber security and responsible AI are necessary to develop certified and compliant systems that are ready to adapt to new regulations. "schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} A specific re
levance of this adaptive approach is specifically considering the fact that representatives of the opposite
 side may capitalize on weaknesses in order to make an esoteric set of attacks, such as membership inferenc
e and gradient leaks, and in the process, to provoke the shortcomings of the currently available privacy-en
hancing technologies. It is thus essential that in future studies, efforts be made to strictly test federat
ed foundation models concerning the emerging threats, such as evasion methods that have the capability of s
pecifically targeting large language models, to ensure that federated foundation models are secure and resi
lient in practical applications. (S. Ali et al., 2025; Aljanabi et al., 2024; Alruwaili et al., 2024; Amich
