It also dwells into various mechanisms of coping with such problems as heterogeneity of data, efficiency of communication and equity of federated recommender systems and how the models can be utilized to effectively deal with the problem of rating bias. Recent trends in federated learning as a recommendation system which include FedRec and FCF, has largely focused on collaborative filtering and matrix factorization of the matrices FedMF also incorporates a homomorphic encoding aspect to transmit gradients in a secure manner. In spite of such developments, many of the existing studies are inclined to dwell on the primitive aspects of equity, bigotry, and risks to system integrity, which play a vital role in the formulation of effective and trustworthy recommender systems. However, the research of fairness, integrity in the circumstances of various attacks is an active research question in spite of the particularity of other studies aimed at enhancing the efficiency of federated recommender systems by accelerating convergence or by using light-weight communication schemes. In addition to that, the foundation models supported by federated recommendation systems represent a shining light to high-performance and privacy despite the fact that the sphere is still at its initial developmental phases. Precisely, the models, on the one hand, take advantages of their widely computerised pre-training knowledge in order to better the quality of the recommendations in which also federated learning maintains the sensitive user interaction data utilised in a fine-tuning process localised. However, the complete capacity of foundation models to the federated recommendation system is achieved with the perception of how their pre-training capabilities can be applied to address the problem of data heterogeneity and serve to optimize the effectiveness of model aggregation. Whereas the recent literature suggests as an application of large language models, the idea of large language models in such a federated structure suggests rather a change in the thinking of data integration, which is not necessitating a complete utilization of the large language models but suggests that it will be driven by a paradigm shift to the complete utilization of the large parameters in data integration at an increased communication cost. /raw/master/csl-citation.json\"} In this part, the available literature on the topic of federated learning
mechanism in recommendation systems is presented and, in particular, the privacy-saving mechanisms and thei
r impact on the performance of the model are discussed. It also dwells into various mechanisms of coping wi
th such problems as heterogeneity of data, efficiency of communication and equity of federated recommender
systems and how the models can be utilized to effectively deal with the problem of rating bias. Recent tren
ds in federated learning as a recommendation system which include FedRec and FCF, has largely focused on co
llaborative filtering and matrix factorization of the matrices FedMF also incorporates a homomorphic encodi
ng aspect to transmit gradients in a secure manner. In spite of such developments, many of the existing stu
dies are inclined to dwell on the primitive aspects of equity, bigotry, and risks to system integrity, whic
h play a vital role in the formulation of effective and trustworthy recommender systems. However, the resea
rch of fairness, integrity in the circumstances of various attacks is an active research question in spite
of the particularity of other studies aimed at enhancing the efficiency of federated recommender systems by
 accelerating convergence or by using light-weight communication schemes. In addition to that, the foundati
on models supported by federated recommendation systems represent a shining light to high-performance and p
rivacy despite the fact that the sphere is still at its initial developmental phases. Precisely, the models
, on the one hand, take advantages of their widely computerised pre-training knowledge in order to better t
he quality of the recommendations in which also federated learning maintains the sensitive user interaction
 data utilised in a fine-tuning process localised. However, the complete capacity of foundation models to t
he federated recommendation system is achieved with the perception of how their pre-training capabilities c
an be applied to address the problem of data heterogeneity and serve to optimize the effectiveness of model
 aggregation. Whereas the recent literature suggests as an application of large language models, the idea o
f large language models in such a federated structure suggests rather a change in the thinking of data inte
gration, which is not necessitating a complete utilization of the large language models but suggests that i
t will be driven by a paradigm shift to the complete utilization of the large parameters in data integratio
n at an increased communication cost. (Z. Chen et al., 2022c; H. Dai et al., 2024; Y. Ding et al., 2024; H.

,\"issued\":{\"date-parts\":[[\"2025\"]]}}}],\"schema\":\"https://github.com/citation-style-language/schema
/raw/master/csl-citation.json\"} In this part, the available literature on the topic of federated learning 
mechanism in recommendation systems is presented and, in particular, the privacy-saving mechanisms and thei
r impact on the performance of the model are discussed. It also dwells into various mechanisms of coping wi
th such problems as heterogeneity of data, efficiency of communication and equity of federated recommender 
systems and how the models can be utilized to effectively deal with the problem of rating bias. Recent tren
ds in federated learning as a recommendation system which include FedRec and FCF, has largely focused on co
llaborative filtering and matrix factorization of the matrices FedMF also incorporates a homomorphic encodi
ng aspect to transmit gradients in a secure manner. In spite of such developments, many of the existing stu
dies are inclined to dwell on the primitive aspects of equity, bigotry, and risks to system integrity, whic
h play a vital role in the formulation of effective and trustworthy recommender systems. However, the resea
rch of fairness, integrity in the circumstances of various attacks is an active research question in spite 
of the particularity of other studies aimed at enhancing the efficiency of federated recommender systems by
 accelerating convergence or by using light-weight communication schemes. In addition to that, the foundati
on models supported by federated recommendation systems represent a shining light to high-performance and p
rivacy despite the fact that the sphere is still at its initial developmental phases. Precisely, the models
, on the one hand, take advantages of their widely computerised pre-training knowledge in order to better t
he quality of the recommendations in which also federated learning maintains the sensitive user interaction
 data utilised in a fine-tuning process localised. However, the complete capacity of foundation models to t
he federated recommendation system is achieved with the perception of how their pre-training capabilities c
an be applied to address the problem of data heterogeneity and serve to optimize the effectiveness of model
 aggregation. Whereas the recent literature suggests as an application of large language models, the idea o
f large language models in such a federated structure suggests rather a change in the thinking of data inte
gration, which is not necessitating a complete utilization of the large language models but suggests that i
t will be driven by a paradigm shift to the complete utilization of the large parameters in data integratio
n at an increased communication cost. (Z. Chen et al., 2022c; H. Dai et al., 2024; Y. Ding et al., 2024; H.

,\"issued\":{\"date-parts\":[[\"2025\"]]}}}],\"schema\":\"https://github.com/citation-style-language/schema
/raw/master/csl-citation.json\"} In this part, the available literature on the topic of federated learning 
mechanism in recommendation systems is presented and, in particular, the privacy-saving mechanisms and thei
r impact on the performance of the model are discussed. It also dwells into various mechanisms of coping wi
th such problems as heterogeneity of data, efficiency of communication and equity of federated recommender 
systems and how the models can be utilized to effectively deal with the problem of rating bias. Recent tren
ds in federated learning as a recommendation system which include FedRec and FCF, has largely focused on co
llaborative filtering and matrix factorization of the matrices FedMF also incorporates a homomorphic encodi
ng aspect to transmit gradients in a secure manner. In spite of such developments, many of the existing stu
dies are inclined to dwell on the primitive aspects of equity, bigotry, and risks to system integrity, whic
h play a vital role in the formulation of effective and trustworthy recommender systems. However, the resea
rch of fairness, integrity in the circumstances of various attacks is an active research question in spite 
of the particularity of other studies aimed at enhancing the efficiency of federated recommender systems by
 accelerating convergence or by using light-weight communication schemes. In addition to that, the foundati
on models supported by federated recommendation systems represent a shining light to high-performance and p
rivacy despite the fact that the sphere is still at its initial developmental phases. Precisely, the models
, on the one hand, take advantages of their widely computerised pre-training knowledge in order to better t
he quality of the recommendations in which also federated learning maintains the sensitive user interaction
 data utilised in a fine-tuning process localised. However, the complete capacity of foundation models to t
he federated recommendation system is achieved with the perception of how their pre-training capabilities c
an be applied to address the problem of data heterogeneity and serve to optimize the effectiveness of model
 aggregation. Whereas the recent literature suggests as an application of large language models, the idea o
f large language models in such a federated structure suggests rather a change in the thinking of data inte
gration, which is not necessitating a complete utilization of the large language models but suggests that i
t will be driven by a paradigm shift to the complete utilization of the large parameters in data integratio
n at an increased communication cost. (Z. Chen et al., 2022c; H. Dai et al., 2024; Y. Ding et al., 2024; H.

/raw/master/csl-citation.json\"} In this part, the available literature on the topic of federated learning mechanism in recommendation systems is presented and, in particular, the privacy-saving mechanisms and their impact on the performance of the model are discussed. It also dwells into various mechanisms of coping with such problems as heterogeneity of data, efficiency of communication and equity of federated recommender systems and how the models can be utilized to effectively deal with the problem of rating bias. Recent trends in federated learning as a recommendation system which include FedRec and FCF, has largely focused on collaborative filtering and matrix factorization of the matrices FedMF also incorporates a homomorphic encoding aspect to transmit gradients in a secure manner. In spite of such developments, many of the existing studies are inclined to dwell on the primitive aspects of equity, bigotry, and risks to system integrity, which play a vital role in the formulation of effective and trustworthy recommender systems. However, the research of fairness, integrity in the circumstances of various attacks is an active research question in spite of the particularity of other studies aimed at enhancing the efficiency of federated recommender systems by accelerating convergence or by using light-weight communication schemes. In addition to that, the foundation models supported by federated recommendation systems represent a shining light to high-performance and privacy despite the fact that the sphere is still at its initial developmental phases. Precisely, the models

```
, on the one hand, take advantages of their widely computerised pre-training knowledge in order to better t
he quality of the recommendations in which also federated learning maintains the sensitive user interaction
 data utilised in a fine-tuning process localised. However, the complete capacity of foundation models to t
he federated recommendation system is achieved with the perception of how their pre-training capabilities c
an be applied to address the problem of data heterogeneity and serve to optimize the effectiveness of model
 aggregation. Whereas the recent literature suggests as an application of large language models, the idea o
f large language models in such a federated structure suggests rather a change in the thinking of data inte
gration, which is not necessitating a complete utilization of the large language models but suggests that i
t will be driven by a paradigm shift to the complete utilization of the large parameters in data integratio
n at an increased communication cost. (Z. Chen et al., 2022c; H. Dai et al., 2024; Y. Ding et al., 2024; H.

,\"issued\":{\"date-parts\":[[\"2025\"]]}}}],\"schema\":\"https://github.com/citation-style-language/schema
/raw/master/csl-citation.json\"} In this part, the available literature on the topic of federated learning
mechanism in recommendation systems is presented and, in particular, the privacy-saving mechanisms and thei
r impact on the performance of the model are discussed. It also dwells into various mechanisms of coping wi
th such problems as heterogeneity of data, efficiency of communication and equity of federated recommender
systems and how the models can be utilized to effectively deal with the problem of rating bias. Recent tren
ds in federated learning as a recommendation system which include FedRec and FCF, has largely focused on co
llaborative filtering and matrix factorization of the matrices FedMF also incorporates a homomorphic encodi
ng aspect to transmit gradients in a secure manner. In spite of such developments, many of the existing stu
dies are inclined to dwell on the primitive aspects of equity, bigotry, and risks to system integrity, whic
h play a vital role in the formulation of effective and trustworthy recommender systems. However, the resea
rch of fairness, integrity in the circumstances of various attacks is an active research question in spite
of the particularity of other studies aimed at enhancing the efficiency of federated recommender systems by
 accelerating convergence or by using light-weight communication schemes. In addition to that, the foundati
on models supported by federated recommendation systems represent a shining light to high-performance and p
rivacy despite the fact that the sphere is still at its initial developmental phases. Precisely, the models
, on the one hand, take advantages of their widely computerised pre-training knowledge in order to better t
he quality of the recommendations in which also federated learning maintains the sensitive user interaction
 data utilised in a fine-tuning process localised. However, the complete capacity of foundation models to t
he federated recommendation system is achieved with the perception of how their pre-training capabilities c
an be applied to address the problem of data heterogeneity and serve to optimize the effectiveness of model
 aggregation. Whereas the recent literature suggests as an application of large language models, the idea o
f large language models in such a federated structure suggests rather a change in the thinking of data inte
gration, which is not necessitating a complete utilization of the large language models but suggests that i
t will be driven by a paradigm shift to the complete utilization of the large parameters in data integratio
n at an increased communication cost. (Z. Chen et al., 2022c; H. Dai et al., 2024; Y. Ding et al., 2024; H.

,\"issued\":{\"date-parts\":[[\"2025\"]]}}}],\"schema\":\"https://github.com/citation-style-language/schema
/raw/master/csl-citation.json\"} In this part, the available literature on the topic of federated learning
mechanism in recommendation systems is presented and, in particular, the privacy-saving mechanisms and thei
r impact on the performance of the model are discussed. It also dwells into various mechanisms of coping wi
th such problems as heterogeneity of data, efficiency of communication and equity of federated recommender
systems and how the models can be utilized to effectively deal with the problem of rating bias. Recent tren
ds in federated learning as a recommendation system which include FedRec and FCF, has largely focused on co
llaborative filtering and matrix factorization of the matrices FedMF also incorporates a homomorphic encodi
ng aspect to transmit gradients in a secure manner. In spite of such developments, many of the existing stu
dies are inclined to dwell on the primitive aspects of equity, bigotry, and risks to system integrity, whic
h play a vital role in the formulation of effective and trustworthy recommender systems. However, the resea
rch of fairness, integrity in the circumstances of various attacks is an active research question in spite
of the particularity of other studies aimed at enhancing the efficiency of federated recommender systems by
 accelerating convergence or by using light-weight communication schemes. In addition to that, the foundati
on models supported by federated recommendation systems represent a shining light to high-performance and p
rivacy despite the fact that the sphere is still at its initial developmental phases. Precisely, the models
, on the one hand, take advantages of their widely computerised pre-training knowledge in order to better t
he quality of the recommendations in which also federated learning maintains the sensitive user interaction
 data utilised in a fine-tuning process localised. However, the complete capacity of foundation models to t
he federated recommendation system is achieved with the perception of how their pre-training capabilities c
an be applied to address the problem of data heterogeneity and serve to optimize the effectiveness of model
 aggregation. Whereas the recent literature suggests as an application of large language models, the idea o
f large language models in such a federated structure suggests rather a change in the thinking of data inte
gration, which is not necessitating a complete utilization of the large language models but suggests that i
t will be driven by a paradigm shift to the complete utilization of the large parameters in data integratio
n at an increased communication cost. (Z. Chen et al., 2022c; H. Dai et al., 2024; Y. Ding et al., 2024; H.

In this part, the available literature on the topic of federated learning mechanism in recommendation systems is presented and, in particular, the privacy-saving mechanisms and their impact on the performance of the model are discussed. It also dwells into various mechanisms of coping with such problems as heterogeneity of data, efficiency of communication and equity of federated recommender systems and how the models can be utilized to effectively deal with the problem of rating bias. Recent trends in federated learning as a recommendation system which include FedRec and FCF, has largely focused on collaborative filtering and matrix factorization of the matrices FedMF also incorporates a homomorphic encoding aspect to transmit gradients in a secure manner. In spite of such developments, many of the existing studies are inclined to dwell on the primitive aspects of equity, bigotry, and risks to system integrity, which play a vital role in the formulation of effective and trustworthy recommender systems. However, the research of fairness, integrity in the circumstances of various attacks is an active research question in spite of the particularity of other studies aimed at enhancing the efficiency of federated recommender systems by accelerating convergence or by using light-weight communication schemes. In addition to that, the foundation models supported by federated recommendation systems represent a shining light to high-performance and privacy despite the fact that the sphere is still at its initial developmental phases. Precisely, the models , on the one hand, take advantages of their widely computerised pre-training knowledge in order to better the quality of the recommendations in which also federated learning maintains the sensitive user interaction data utilised in a fine-tuning process localised. However, the complete capacity of foundation models to the federated recommendation system is achieved with the perception of how their pre-training capabilities can be applied to address the problem of data heterogeneity and serve to optimize the effectiveness of model aggregation. Whereas the recent literature suggests as an application of large language models, the idea of large language models in such a federated structure suggests rather a change in the thinking of data integration, which is not necessitating a complete utilization of the large language models but suggests that it will be driven by a paradigm shift to the complete utilization of the large parameters in data integration at an increased communication cost. mechanism in recommendation systems is presented and, in particular, the privacy-saving mechanisms and their impact on the performance of the model are discussed. It also dwells into various mechanisms of coping with such problems as heterogeneity of data, efficiency of communication and equity of federated recommender systems and how the models can be utilized to effectively deal with the problem of rating bias. Recent trends in federated learning as a recommendation system which include FedRec and FCF, has largely focused on collaborative filtering and matrix factorization of the matrices FedMF also incorporates a homomorphic encoding aspect to transmit gradients in a secure manner. In spite of such developments, many of the existing studies are inclined to dwell on the primitive aspects of equity, bigotry, and risks to system integrity, which play a vital role in the formulation of effective and trustworthy recommender systems. However, the research of fairness, integrity in the circumstances of various attacks is an active research question in spite of the particularity of other studies aimed at enhancing the efficiency of federated recommender systems by accelerating convergence or by using light-weight communication schemes. In addition to that, the foundation models supported by federated recommendation systems represent a shining light to high-performance and privacy despite the fact that the sphere is still at its initial developmental phases. Precisely, the models, on the one hand, take advantages of their widely computerised pre-training knowledge in order to better the quality of the recommendations in which also federated learning maintains the sensitive user interaction data utilised in a fine-tuning process localised. However, the complete capacity of foundation models to the federated recommendation system is achieved with the perception of how their pre-training capabilities can be applied to address the problem of data heterogeneity and serve to optimize the effectiveness of model aggregation. Whereas the recent literature suggests as an application of large language models, the idea of large language models in such a federated structure suggests rather a change in the thinking of data integration, which is not necessitating a complete utilization of the large language models but suggests that it will be driven by a paradigm shift to the complete utilization of the large parameters in data integration at an increased communication cost. mily\":\"Yang\",\"given\":\"Yun\"}],\"issued\":{\"date-parts\":[[\"2017\"]]}}}],\"schema\":\"https://github
.com/citation-style-language/schema/raw/master/csl-citation.json\"} Other issues, raised with this integrat
ion, include unfamiliar issues regarding privacy-security trade-offs as well as non-IID data distribution m
anagement issues that are situation in federated settings. Furthermore, in spite of the fact that federated
 learning has privacy-friendly properties, nowadays the federated recommendation systems are scarcer in the
ir abilities, such as the impossibility of working with non-IID data distributions, and reduced the perform
ance of the models under the influence of privacy-saving processes. As a way of managing those problems, th
e necessity to shift to more developed federated learning models and secure a high rank of dealing with dif
ferent data characteristics and high-quality recommendations and high privacy policies. Development of fram
eworks that can ensure the impartiality and fairness of the recommendations, privacy of the users and discl
osure of the outcomes is significant in improving the future recommender systems. In particular, the introd
uction of large language models and foundation models to federated recommendation systems introduces the ne
w paradigm in an attempt to increase the scope of the generalization of such systems, as well as the qualit
y of its recommendations, which are limited by the classical approaches to collaborative filtering. It is t
hrough this integration that the foundation models possess vast pre-trained knowledge that allows it to be
capable of solving data sources sparsity and cold-start problems and federated learning provides privacy re
assuring form of personalized recommendations. (Azezew, 2025; Bakhtiari, 2025a; Bhalla, 2025; Carrasco Ramí

mily\":\"Yang\",\"given\":\"Yun\"}],\"issued\":{\"date-parts\":[[\"2017\"]]}}}],\"schema\":\"https://github
.com/citation-style-language/schema/raw/master/csl-citation.json\"} Other issues, raised with this integrat
ion, include unfamiliar issues regarding privacy-security trade-offs as well as non-IID data distribution m
anagement issues that are situation in federated settings. Furthermore, in spite of the fact that federated
 learning has privacy-friendly properties, nowadays the federated recommendation systems are scarcer in the
ir abilities, such as the impossibility of working with non-IID data distributions, and reduced the perform
ance of the models under the influence of privacy-saving processes. As a way of managing those problems, th
e necessity to shift to more developed federated learning models and secure a high rank of dealing with dif
ferent data characteristics and high-quality recommendations and high privacy policies. Development of fram
eworks that can ensure the impartiality and fairness of the recommendations, privacy of the users and discl
osure of the outcomes is significant in improving the future recommender systems. In particular, the introd
uction of large language models and foundation models to federated recommendation systems introduces the ne
w paradigm in an attempt to increase the scope of the generalization of such systems, as well as the qualit
y of its recommendations, which are limited by the classical approaches to collaborative filtering. It is t
hrough this integration that the foundation models possess vast pre-trained knowledge that allows it to be
capable of solving data sources sparsity and cold-start problems and federated learning provides privacy re
assuring form of personalized recommendations. (Azezew, 2025; Bakhtiari, 2025a; Bhalla, 2025; Carrasco Ramí

Other issues, raised with this integration, include unfamiliar issues regarding privacy-security trade-offs as well as non-IID data distribution management issues that are situation in federated settings. Furthermore, in spite of the fact that federated learning has privacy-friendly properties, nowadays the federated recommendation systems are scarcer in their abilities, such as the impossibility of working with non-IID data distributions, and reduced the performance of the models under the influence of privacy-saving processes. As a way of managing those problems, the necessity to shift to more developed federated learning models and secure a high rank of dealing with different data characteristics and high-quality recommendations and high privacy policies. Development of frameworks that can ensure the impartiality and fairness of the recommendations, privacy of the users and disclosure of the outcomes is significant in improving the future recommender systems. In particular, the introduction of large language models and foundation models to federated recommendation systems introduces the new paradigm in an attempt to increase the scope of the generalization of such systems, as well as the quality of its recommendations, which are limited by the classical approaches to collaborative filtering. It is through this integration that the foundation models possess vast pre-trained knowledge that allows it to be capable of solving data sources sparsity and cold-start problems and federated learning provides privacy re

Furthermore, in spite of the fact that federated learning has privacy-friendly properties, nowadays the federated recommendation systems are scarcer in their abilities, such as the impossibility of working with non-IID data distributions, and reduced the performance of the models under the influence of privacy-saving processes. As a way of managing those problems, the necessity to shift to more developed federated learning models and secure a high rank of dealing with different data characteristics and high-quality recommendations and high privacy policies. Development of frameworks that can ensure the impartiality and fairness of the recommendations, privacy of the users and disclosure of the outcomes is significant in improving the future recommender systems. In particular, the introduction of large language models and foundation models to federated recommendation systems introduces the new paradigm in an attempt to increase the scope of the generalization of such systems, as well as the quality of its recommendations, which are limited by the classical approaches to collaborative filtering. It is through this integration that the foundation models possess vast pre-trained knowledge that allows it to be capable of solving data sources sparsity and cold-start problems and federated learning provides privacy reassuring form of personalized recommendations. .com/citation-style-language/schema/raw/master/csl-citation.json\"} Other issues, raised with this integrat
ion, include unfamiliar issues regarding privacy-security trade-offs as well as non-IID data distribution m
anagement issues that are situation in federated settings. Furthermore, in spite of the fact that federated
 learning has privacy-friendly properties, nowadays the federated recommendation systems are scarcer in the
ir abilities, such as the impossibility of working with non-IID data distributions, and reduced the perform
ance of the models under the influence of privacy-saving processes. As a way of managing those problems, th
e necessity to shift to more developed federated learning models and secure a high rank of dealing with dif
ferent data characteristics and high-quality recommendations and high privacy policies. Development of fram
eworks that can ensure the impartiality and fairness of the recommendations, privacy of the users and discl
osure of the outcomes is significant in improving the future recommender systems. In particular, the introd
uction of large language models and foundation models to federated recommendation systems introduces the ne
w paradigm in an attempt to increase the scope of the generalization of such systems, as well as the qualit
y of its recommendations, which are limited by the classical approaches to collaborative filtering. It is t
hrough this integration that the foundation models possess vast pre-trained knowledge that allows it to be
capable of solving data sources sparsity and cold-start problems and federated learning provides privacy re
assuring form of personalized recommendations. (Azezew, 2025; Bakhtiari, 2025a; Bhalla, 2025; Carrasco Ramí

e necessity to shift to more developed federated learning models and secure a high rank of dealing with dif
ferent data characteristics and high-quality recommendations and high privacy policies. Development of fram
eworks that can ensure the impartiality and fairness of the recommendations, privacy of the users and discl
osure of the outcomes is significant in improving the future recommender systems. In particular, the introd
uction of large language models and foundation models to federated recommendation systems introduces the ne
w paradigm in an attempt to increase the scope of the generalization of such systems, as well as the qualit
y of its recommendations, which are limited by the classical approaches to collaborative filtering. It is t
hrough this integration that the foundation models possess vast pre-trained knowledge that allows it to be
capable of solving data sources sparsity and cold-start problems and federated learning provides privacy re
assuring form of personalized recommendations. (Azezew, 2025; Bakhtiari, 2025a; Bhalla, 2025; Carrasco Ramí

Furthermore, in spite of the fact that federated learning has privacy-friendly properties, nowadays the federated recommendation systems are scarcer in their abilities, such as the impossibility of working with non-IID data distributions, and reduced the performance of the models under the influence of privacy-saving processes. As a way of managing those problems, the necessity to shift to more developed federated learning models and secure a high rank of dealing with different data characteristics and high-quality recommendations and high privacy policies. Development of frameworks that can ensure the impartiality and fairness of the recommendations, privacy of the users and disclosure of the outcomes is significant in improving the future recommender systems. In particular, the introduction of large language models and foundation models to federated recommendation systems introduces the new paradigm in an attempt to increase the scope of the generalization of such systems, as well as the quality of its recommendations, which are limited by the classical approaches to collaborative filtering. It is through this integration that the foundation models possess vast pre-trained knowledge that allows it to be capable of solving data sources sparsity and cold-start problems and federated learning provides privacy reassuring form of personalized recommendations. Other issues, raised with this integration, include unfamiliar issues regarding privacy-security trade-offs as well as non-IID data distribution management issues that are situation in federated settings. Furthermore, in spite of the fact that federated learning has privacy-friendly properties, nowadays the federated recommendation systems are scarcer in their abilities, such as the impossibility of working with non-IID data distributions, and reduced the performance of the models under the influence of privacy-saving processes. As a way of managing those problems, the necessity to shift to more developed federated learning models and secure a high rank of dealing with different data characteristics and high-quality recommendations and high privacy policies. Development of frameworks that can ensure the impartiality and fairness of the recommendations, privacy of the users and disclosure of the outcomes is significant in improving the future recommender systems. In particular, the introduction of large language models and foundation models to federated recommendation systems introduces the new paradigm in an attempt to increase the scope of the generalization of such systems, as well as the quality of its recommendations, which are limited by the classical approaches to collaborative filtering. It is through this integration that the foundation models possess vast pre-trained knowledge that allows it to be capable of solving data sources sparsity and cold-start problems and federated learning provides privacy reassuring form of personalized recommendations. Other issues, raised with this integration, include unfamiliar issues regarding privacy-security trade-offs as well as non-IID data distribution management issues that are situation in federated settings. Furthermore, in spite of the fact that federated learning has privacy-friendly properties, nowadays the federated recommendation systems are scarcer in their abilities, such as the impossibility of working with non-IID data distributions, and reduced the performance of the models under the influence of privacy-saving processes. As a way of managing those problems, the necessity to shift to more developed federated learning models and secure a high rank of dealing with different data characteristics and high-quality recommendations and high privacy policies. Development of frameworks that can ensure the impartiality and fairness of the recommendations, privacy of the users and disclosure of the outcomes is significant in improving the future recommender systems. In particular, the introduction of large language models and foundation models to federated recommendation systems introduces the new paradigm in an attempt to increase the scope of the generalization of such systems, as well as the quality of its recommendations, which are limited by the classical approaches to collaborative filtering. It is through this integration that the foundation models possess vast pre-trained knowledge that allows it to be capable of solving data sources sparsity and cold-start problems and federated learning provides privacy reassuring form of personalized recommendations. .com/citation-style-language/schema/raw/master/csl-citation.json\"} Other issues, raised with this integrat

```
ion, include unfamiliar issues regarding privacy-security trade-offs as well as non-IID data distribution m
anagement issues that are situation in federated settings. Furthermore, in spite of the fact that federated
 learning has privacy-friendly properties, nowadays the federated recommendation systems are scarcer in the
ir abilities, such as the impossibility of working with non-IID data distributions, and reduced the perform
ance of the models under the influence of privacy-saving processes. As a way of managing those problems, th
e necessity to shift to more developed federated learning models and secure a high rank of dealing with dif
ferent data characteristics and high-quality recommendations and high privacy policies. Development of fram
eworks that can ensure the impartiality and fairness of the recommendations, privacy of the users and discl
osure of the outcomes is significant in improving the future recommender systems. In particular, the introd
uction of large language models and foundation models to federated recommendation systems introduces the ne
w paradigm in an attempt to increase the scope of the generalization of such systems, as well as the qualit
y of its recommendations, which are limited by the classical approaches to collaborative filtering. It is t
hrough this integration that the foundation models possess vast pre-trained knowledge that allows it to be
capable of solving data sources sparsity and cold-start problems and federated learning provides privacy re
assuring form of personalized recommendations. (Azezew, 2025; Bakhtiari, 2025a; Bhalla, 2025; Carrasco Ramí

Furthermore, in spite of the fact that federated learning has privacy-friendly properties, nowadays the federated recommendation systems are scarcer in their abilities, such as the impossibility of working with non-IID data distributions, and reduced the performance of the models under the influence of privacy-saving processes. As a way of managing those problems, the necessity to shift to more developed federated learning models and secure a high rank of dealing with different data characteristics and high-quality recommendations and high privacy policies. Development of frameworks that can ensure the impartiality and fairness of the recommendations, privacy of the users and disclosure of the outcomes is significant in improving the future recommender systems. In particular, the introduction of large language models and foundation models to federated recommendation systems introduces the new paradigm in an attempt to increase the scope of the generalization of such systems, as well as the quality of its recommendations, which are limited by the classical approaches to collaborative filtering. It is through this integration that the foundation models possess vast pre-trained knowledge that allows it to be capable of solving data sources sparsity and cold-start problems and federated learning provides privacy reassuring form of personalized recommendations. mily\":\"Yang\",\"given\":\"Yun\"}],\"issued\":{\"date-parts\":[[\"2017\"]]}}],\"schema\":\"https://github
.com/citation-style-language/schema/raw/master/csl-citation.json\"} Other issues, raised with this integrat
ion, include unfamiliar issues regarding privacy-security trade-offs as well as non-IID data distribution m
anagement issues that are situation in federated settings. Furthermore, in spite of the fact that federated
 learning has privacy-friendly properties, nowadays the federated recommendation systems are scarcer in the
ir abilities, such as the impossibility of working with non-IID data distributions, and reduced the perform
ance of the models under the influence of privacy-saving processes. As a way of managing those problems, th
e necessity to shift to more developed federated learning models and secure a high rank of dealing with dif
ferent data characteristics and high-quality recommendations and high privacy policies. Development of fram
eworks that can ensure the impartiality and fairness of the recommendations, privacy of the users and discl
osure of the outcomes is significant in improving the future recommender systems. In particular, the introd
uction of large language models and foundation models to federated recommendation systems introduces the ne
w paradigm in an attempt to increase the scope of the generalization of such systems, as well as the qualit
y of its recommendations, which are limited by the classical approaches to collaborative filtering. It is t
hrough this integration that the foundation models possess vast pre-trained knowledge that allows it to be
capable of solving data sources sparsity and cold-start problems and federated learning provides privacy re
assuring form of personalized recommendations. (Azezew, 2025; Bakhtiari, 2025a; Bhalla, 2025; Carrasco Ramí

.com/citation-style-language/schema/raw/master/csl-citation.json\"} Other issues, raised with this integrat
ion, include unfamiliar issues regarding privacy-security trade-offs as well as non-IID data distribution m
anagement issues that are situation in federated settings. Furthermore, in spite of the fact that federated
 learning has privacy-friendly properties, nowadays the federated recommendation systems are scarcer in the
ir abilities, such as the impossibility of working with non-IID data distributions, and reduced the perform
ance of the models under the influence of privacy-saving processes. As a way of managing those problems, th
e necessity to shift to more developed federated learning models and secure a high rank of dealing with dif
ferent data characteristics and high-quality recommendations and high privacy policies. Development of fram
eworks that can ensure the impartiality and fairness of the recommendations, privacy of the users and discl
osure of the outcomes is significant in improving the future recommender systems. In particular, the introd
uction of large language models and foundation models to federated recommendation systems introduces the ne
w paradigm in an attempt to increase the scope of the generalization of such systems, as well as the qualit
y of its recommendations, which are limited by the classical approaches to collaborative filtering. It is t
hrough this integration that the foundation models possess vast pre-trained knowledge that allows it to be
capable of solving data sources sparsity and cold-start problems and federated learning provides privacy re
assuring form of personalized recommendations. (Azezew, 2025; Bakhtiari, 2025a; Bhalla, 2025; Carrasco Ramí

Other issues, raised with this integration, include unfamiliar issues regarding privacy-security trade-offs as well as non-IID data distribution management issues that are situation in federated settings. Furthermore, in spite of the fact that federated learning has privacy-friendly properties, nowadays the federated recommendation systems are scarcer in their abilities, such as the impossibility of working with non-IID data distributions, and reduced the performance of the models under the influence of privacy-saving processes. As a way of managing those problems, the necessity to shift to more developed federated learning models and secure a high rank of dealing with different data characteristics and high-quality recommendations and high privacy policies. Development of frameworks that can ensure the impartiality and fairness of the recommendations, privacy of the users and disclosure of the outcomes is significant in improving the future recommender systems. In particular, the introduction of large language models and foundation models to federated recommendation systems introduces the new paradigm in an attempt to increase the scope of the generalization of such systems, as well as the quality of its recommendations, which are limited by the classical approaches to collaborative filtering. It is through this integration that the foundation models possess vast pre-trained knowledge that allows it to be capable of solving data sources sparsity and cold-start problems and federated learning provides privacy reassuring form of personalized recommendations. Other issues, raised with this integration, include unfamiliar issues regarding privacy-security trade-offs as well as non-IID data distribution management issues that are situation in federated settings. Furthermore, in spite of the fact that federated learning has privacy-friendly properties, nowadays the federated recommendation systems are scarcer in their abilities, such as the impossibility of working with non-IID data distributions, and reduced the performance of the models under the influence of privacy-saving processes. As a way of managing those problems, the necessity to shift to more developed federated learning models and secure a high rank of dealing with different data characteristics and high-quality recommendations and high privacy policies. Development of frameworks that can ensure the impartiality and fairness of the recommendations, privacy of the users and disclosure of the outcomes is significant in improving the future recommender systems. In particular, the introduction of large language models and foundation models to federated recommendation systems introduces the new paradigm in an attempt to increase the scope of the generalization of such systems, as well as the quality of its recommendations, which are limited by the classical approaches to collaborative filtering. It is through this integration that the foundation models possess vast pre-trained knowledge that allows it to be capable of solving data sources sparsity and cold-start problems and federated learning provides privacy reassuring form of personalized recommendations. "schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} Indicatively,
 with an example, federated adaptation mechanisms can be employed to permit desire -shift variations amidst
 a user in an agreeable and privacy conscious means with featherweight customized adjustment on client devi
ces. One significant benefit of the approach is that the communication overhead of exchanging large-sized m
odel parameters is reduced and, therefore, improves resource-limited mobile environments. Moreover, another
 potential solution to the suggested system enhancement suggests implementing large language models into th
e federated learning systems because large language models have an opportunity to leverage their large pre-
trainings and generalization capabilities to address the issue of data scarcity and increase personalizatio
n. This remedy however comes at a cost in that new techniques are necessary to interdiscipline the computat
ional demands of large-scale models with privacy guarantees provided by the federated learning in the situa
tion of resource-limited environments. The decrease of the data sparsity and heterogeneity of the client de
vices which typically leads to diminished model performance in classical federated systems of recommendatio
n is another issue of the field importance. More research on the ability of such models to be effectively t
uned to decentralized data and the fact that their privacy processes do not attract the attention of the qu
ality of recommendations and fairness can also be conducted. The Federation Foundation Models development p
resupposes these issues with the help of collaborative learning in federated structures toward the improved
 model performance and data privacy as well as the possibility to develop more personalized and context-sen
sitive models. It has the possibility of increasing data and has a smaller computational requirement, with
the pre-training and data augmentation techniques, and serves as an option to the problem, such as the shor
tage of data, variability in computation, etc. More so, federated foundation models offer a robust privacy-
preserving scheme to collaboratively fine-tune models with varying disparate and decentralized and non-IID
data, combining parameter-efficient and personalization models to decrease the communication and computatio
n expenses. (Abdel-Sater \u0026 Hamza, 2024; Bakhtiari, 2025b; Bandara, 2025; S. Chen, 2024; Z. Jiang et al

One significant benefit of the approach is that the communication overhead of exchanging large-sized model parameters is reduced and, therefore, improves resource-limited mobile environments. Moreover, another potential solution to the suggested system enhancement suggests implementing large language models into the federated learning systems because large language models have an opportunity to leverage their large pre-trainings and generalization capabilities to address the issue of data scarcity and increase personalization. This remedy however comes at a cost in that new techniques are necessary to interdiscipline the computational demands of large-scale models with privacy guarantees provided by the federated learning in the situation of resource-limited environments. The decrease of the data sparsity and heterogeneity of the client devices which typically leads to diminished model performance in classical federated systems of recommendation is another issue of the field importance. More research on the ability of such models to be effectively tuned to decentralized data and the fact that their privacy processes do not attract the attention of the quality of recommendations and fairness can also be conducted. The Federation Foundation Models development presupposes these issues with the help of collaborative learning in federated structures toward the improved model performance and data privacy as well as the possibility to develop more personalized and context-sensitive models. It has the possibility of increasing data and has a smaller computational requirement, with the pre-training and data augmentation techniques, and serves as an option to the problem, such as the shortage of data, variability in computation, etc. More so, federated foundation models offer a robust privacy-preserving scheme to collaboratively fine-tune models with varying disparate and decentralized and non-IID data, combining parameter-efficient and personalization models to decrease the communication and computation expenses. "schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} Indicatively,
 with an example, federated adaptation mechanisms can be employed to permit desire -shift variations amidst
 a user in an agreeable and privacy conscious means with featherweight customized adjustment on client devi
ces. One significant benefit of the approach is that the communication overhead of exchanging large-sized m
odel parameters is reduced and, therefore, improves resource-limited mobile environments. Moreover, another
 potential solution to the suggested system enhancement suggests implementing large language models into th
e federated learning systems because large language models have an opportunity to leverage their large pre-
trainings and generalization capabilities to address the issue of data scarcity and increase personalizatio
n. This remedy however comes at a cost in that new techniques are necessary to interdiscipline the computat
ional demands of large-scale models with privacy guarantees provided by the federated learning in the situa
tion of resource-limited environments. The decrease of the data sparsity and heterogeneity of the client de
vices which typically leads to diminished model performance in classical federated systems of recommendatio
n is another issue of the field importance. More research on the ability of such models to be effectively t
uned to decentralized data and the fact that their privacy processes do not attract the attention of the qu
ality of recommendations and fairness can also be conducted. The Federation Foundation Models development p
resupposes these issues with the help of collaborative learning in federated structures toward the improved
 model performance and data privacy as well as the possibility to develop more personalized and context-sen
sitive models. It has the possibility of increasing data and has a smaller computational requirement, with
the pre-training and data augmentation techniques, and serves as an option to the problem, such as the shor
tage of data, variability in computation, etc. More so, federated foundation models offer a robust privacy-
preserving scheme to collaboratively fine-tune models with varying disparate and decentralized and non-IID
data, combining parameter-efficient and personalization models to decrease the communication and computatio
n expenses. (Abdel-Sater \u0026 Hamza, 2024; Bakhtiari, 2025b; Bandara, 2025; S. Chen, 2024; Z. Jiang et al

Fine-Tuning of Artificial Intelligence (AI) Foundation Models With Federated Learning, Differential Privacy, Offsite Tuning, and Parameter-Efficient Fine-Tuning (PEFT)\",\"author\":[{\"family\":\"Zhao\",\"given\":\"Jun\"}],\"issued\":{\"date-parts\":[[\"2023\"]]}}}],\"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} Indicatively, with an example, federated adaptation mechanisms can be employed to permit desire -shift variations amidst a user in an agreeable and privacy conscious means with featherweight customized adjustment on client devices. One significant benefit of the approach is that the communication overhead of exchanging large-sized model parameters is reduced and, therefore, improves resource-limited mobile environments. Moreover, another potential solution to the suggested system enhancement suggests implementing large language models into the federated learning systems because large language models have an opportunity to leverage their large pre-trainings and generalization capabilities to address the issue of data scarcity and increase personalization. This remedy however comes at a cost in that new techniques are necessary to interdiscipline the computational demands of large-scale models with privacy guarantees provided by the federated learning in the situation of resource-limited environments. The decrease of the data sparsity and heterogeneity of the client devices which typically leads to diminished model performance in classical federated systems of recommendation is another issue of the field importance. More research on the ability of such models to be effectively tuned to decentralized data and the fact that their privacy processes do not attract the attention of the quality of recommendations and fairness can also be conducted. The Federation Foundation Models development presupposes these issues with the help of collaborative learning in federated structures toward the improved model performance and data privacy as well as the possibility to develop more personalized and context-sensitive models. It has the possibility of increasing data and has a smaller computational requirement, with the pre-training and data augmentation techniques, and serves as an option to the problem, such as the shortage of data, variability in computation, etc. More so, federated foundation models offer a robust privacy-preserving scheme to collaboratively fine-tune models with varying disparate and decentralized and non-IID data, combining parameter-efficient and personalization models to decrease the communication and computation expenses. (PEFT)\",\"author\":[{\"family\":\"Zhao\",\"given\":\"Jun\"}],\"issued\":{\"date-parts\":[[\"2023\"]]}}}],\"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} Indicatively, with an example, federated adaptation mechanisms can be employed to permit desire -shift variations amidst a user in an agreeable and privacy conscious means with featherweight customized adjustment on client devices. One significant benefit of the approach is that the communication overhead of exchanging large-sized model parameters is reduced and, therefore, improves resource-limited mobile environments. Moreover, another potential solution to the suggested system enhancement suggests implementing large language models into the federated learning systems because large language models have an opportunity to leverage their large pre-trainings and generalization capabilities to address the issue of data scarcity and increase personalization. This remedy however comes at a cost in that new techniques are necessary to interdiscipline the computational demands of large-scale models with privacy guarantees provided by the federated learning in the situation of resource-limited environments. The decrease of the data sparsity and heterogeneity of the client devices which typically leads to diminished model performance in classical federated systems of recommendation is another issue of the field importance. More research on the ability of such models to be effectively t

uned to decentralized data and the fact that their privacy processes do not attract the attention of the qu
ality of recommendations and fairness can also be conducted. The Federation Foundation Models development p
resupposes these issues with the help of collaborative learning in federated structures toward the improved
 model performance and data privacy as well as the possibility to develop more personalized and context-sen
sitive models. It has the possibility of increasing data and has a smaller computational requirement, with
the pre-training and data augmentation techniques, and serves as an option to the problem, such as the shor
tage of data, variability in computation, etc. More so, federated foundation models offer a robust privacy-
preserving scheme to collaboratively fine-tune models with varying disparate and decentralized and non-IID
data, combining parameter-efficient and personalization models to decrease the communication and computatio
n expenses. (Abdel-Sater \u0026 Hamza, 2024; Bakhtiari, 2025b; Bandara, 2025; S. Chen, 2024; Z. Jiang et al

"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} Indicatively,
 with an example, federated adaptation mechanisms can be employed to permit desire -shift variations amidst
 a user in an agreeable and privacy conscious means with featherweight customized adjustment on client devi
ces. One significant benefit of the approach is that the communication overhead of exchanging large-sized m
odel parameters is reduced and, therefore, improves resource-limited mobile environments. Moreover, another
 potential solution to the suggested system enhancement suggests implementing large language models into th
e federated learning systems because large language models have an opportunity to leverage their large pre-
trainings and generalization capabilities to address the issue of data scarcity and increase personalizatio
n. This remedy however comes at a cost in that new techniques are necessary to interdiscipline the computat
ional demands of large-scale models with privacy guarantees provided by the federated learning in the situa
tion of resource-limited environments. The decrease of the data sparsity and heterogeneity of the client de
vices which typically leads to diminished model performance in classical federated systems of recommendatio
n is another issue of the field importance. More research on the ability of such models to be effectively t
uned to decentralized data and the fact that their privacy processes do not attract the attention of the qu
ality of recommendations and fairness can also be conducted. The Federation Foundation Models development p
resupposes these issues with the help of collaborative learning in federated structures toward the improved
 model performance and data privacy as well as the possibility to develop more personalized and context-sen
sitive models. It has the possibility of increasing data and has a smaller computational requirement, with
the pre-training and data augmentation techniques, and serves as an option to the problem, such as the shor
tage of data, variability in computation, etc. More so, federated foundation models offer a robust privacy-
preserving scheme to collaboratively fine-tune models with varying disparate and decentralized and non-IID
data, combining parameter-efficient and personalization models to decrease the communication and computatio
n expenses. (Abdel-Sater \u0026 Hamza, 2024; Bakhtiari, 2025b; Bandara, 2025; S. Chen, 2024; Z. Jiang et al

 Models With Federated Learning, Differential Privacy, Offsite Tuning, and Parameter-Efficient Fine-Tuning
(PEFT)\",\"author\":[{\"family\":\"Zhao\",\"given\":\"Jun\"}],\"issued\":{\"date-parts\":[[\"2023\"]]}}}],\
"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} Indicatively,
 with an example, federated adaptation mechanisms can be employed to permit desire -shift variations amidst
 a user in an agreeable and privacy conscious means with featherweight customized adjustment on client devi
ces. One significant benefit of the approach is that the communication overhead of exchanging large-sized m
odel parameters is reduced and, therefore, improves resource-limited mobile environments. Moreover, another
 potential solution to the suggested system enhancement suggests implementing large language models into th
e federated learning systems because large language models have an opportunity to leverage their large pre-
trainings and generalization capabilities to address the issue of data scarcity and increase personalizatio
n. This remedy however comes at a cost in that new techniques are necessary to interdiscipline the computat
ional demands of large-scale models with privacy guarantees provided by the federated learning in the situa
tion of resource-limited environments. The decrease of the data sparsity and heterogeneity of the client de
vices which typically leads to diminished model performance in classical federated systems of recommendatio
n is another issue of the field importance. More research on the ability of such models to be effectively t
uned to decentralized data and the fact that their privacy processes do not attract the attention of the qu
ality of recommendations and fairness can also be conducted. The Federation Foundation Models development p
resupposes these issues with the help of collaborative learning in federated structures toward the improved
 model performance and data privacy as well as the possibility to develop more personalized and context-sen
sitive models. It has the possibility of increasing data and has a smaller computational requirement, with
the pre-training and data augmentation techniques, and serves as an option to the problem, such as the shor
tage of data, variability in computation, etc. More so, federated foundation models offer a robust privacy-
preserving scheme to collaboratively fine-tune models with varying disparate and decentralized and non-IID
data, combining parameter-efficient and personalization models to decrease the communication and computatio
n expenses. (Abdel-Sater \u0026 Hamza, 2024; Bakhtiari, 2025b; Bandara, 2025; S. Chen, 2024; Z. Jiang et al

(PEFT)\",\"author\":[{\"family\":\"Zhao\",\"given\":\"Jun\"}],\"issued\":{\"date-parts\":[[\"2023\"]]}}}],\
"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} Indicatively,
 with an example, federated adaptation mechanisms can be employed to permit desire -shift variations amidst
 a user in an agreeable and privacy conscious means with featherweight customized adjustment on client devi
ces. One significant benefit of the approach is that the communication overhead of exchanging large-sized m
odel parameters is reduced and, therefore, improves resource-limited mobile environments. Moreover, another
 potential solution to the suggested system enhancement suggests implementing large language models into th
e federated learning systems because large language models have an opportunity to leverage their large pre-
trainings and generalization capabilities to address the issue of data scarcity and increase personalizatio
n. This remedy however comes at a cost in that new techniques are necessary to interdiscipline the computat
ional demands of large-scale models with privacy guarantees provided by the federated learning in the situa
tion of resource-limited environments. The decrease of the data sparsity and heterogeneity of the client de
vices which typically leads to diminished model performance in classical federated systems of recommendatio
n is another issue of the field importance. More research on the ability of such models to be effectively t
uned to decentralized data and the fact that their privacy processes do not attract the attention of the qu
ality of recommendations and fairness can also be conducted. The Federation Foundation Models development p
resupposes these issues with the help of collaborative learning in federated structures toward the improved
 model performance and data privacy as well as the possibility to develop more personalized and context-sen
sitive models. It has the possibility of increasing data and has a smaller computational requirement, with
the pre-training and data augmentation techniques, and serves as an option to the problem, such as the shor
tage of data, variability in computation, etc. More so, federated foundation models offer a robust privacy-
preserving scheme to collaboratively fine-tune models with varying disparate and decentralized and non-IID
data, combining parameter-efficient and personalization models to decrease the communication and computatio
n expenses. (Abdel-Sater \u0026 Hamza, 2024; Bakhtiari, 2025b; Bandara, 2025; S. Chen, 2024; Z. Jiang et al

(PEFT)\",\"author\":[{\"family\":\"Zhao\",\"given\":\"Jun\"}],\"issued\":{\"date-parts\":[[\"2023\"]]}}}],\
"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} Indicatively,
 with an example, federated adaptation mechanisms can be employed to permit desire -shift variations amidst
 a user in an agreeable and privacy conscious means with featherweight customized adjustment on client devi
ces. One significant benefit of the approach is that the communication overhead of exchanging large-sized m
odel parameters is reduced and, therefore, improves resource-limited mobile environments. Moreover, another
 potential solution to the suggested system enhancement suggests implementing large language models into th
e federated learning systems because large language models have an opportunity to leverage their large pre-
trainings and generalization capabilities to address the issue of data scarcity and increase personalizatio
n. This remedy however comes at a cost in that new techniques are necessary to interdiscipline the computat
ional demands of large-scale models with privacy guarantees provided by the federated learning in the situa
tion of resource-limited environments. The decrease of the data sparsity and heterogeneity of the client de
vices which typically leads to diminished model performance in classical federated systems of recommendatio
n is another issue of the field importance. More research on the ability of such models to be effectively t
uned to decentralized data and the fact that their privacy processes do not attract the attention of the qu
ality of recommendations and fairness can also be conducted. The Federation Foundation Models development p
resupposes these issues with the help of collaborative learning in federated structures toward the improved
 model performance and data privacy as well as the possibility to develop more personalized and context-sen
sitive models. It has the possibility of increasing data and has a smaller computational requirement, with 
the pre-training and data augmentation techniques, and serves as an option to the problem, such as the shor
tage of data, variability in computation, etc. More so, federated foundation models offer a robust privacy-
preserving scheme to collaboratively fine-tune models with varying disparate and decentralized and non-IID 
data, combining parameter-efficient and personalization models to decrease the communication and computatio
n expenses. (Abdel-Sater \u0026 Hamza, 2024; Bakhtiari, 2025b; Bandara, 2025; S. Chen, 2024; Z. Jiang et al

ality of recommendations and fairness can also be conducted. The Federation Foundation Models development p
resupposes these issues with the help of collaborative learning in federated structures toward the improved
 model performance and data privacy as well as the possibility to develop more personalized and context-sen
sitive models. It has the possibility of increasing data and has a smaller computational requirement, with
the pre-training and data augmentation techniques, and serves as an option to the problem, such as the shor
tage of data, variability in computation, etc. More so, federated foundation models offer a robust privacy-
preserving scheme to collaboratively fine-tune models with varying disparate and decentralized and non-IID
data, combining parameter-efficient and personalization models to decrease the communication and computatio
n expenses. (Abdel-Sater \u0026 Hamza, 2024; Bakhtiari, 2025b; Bandara, 2025; S. Chen, 2024; Z. Jiang et al

Fine-Tuning of Artificial Intelligence (AI) Foundation Models With Federated Learning, Differential Privacy, Offsite Tuning, and Parameter-Efficient Fine-Tuning (PEFT)\",\"author\":[{\"family\":\"Zhao\",\"given\":\"Jun\"}],\"issued\":{\"date-parts\":[[\"2023\"]]}}}],\"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} Indicatively, with an example, federated adaptation mechanisms can be employed to permit desire -shift variations amidst a user in an agreeable and privacy conscious means with featherweight customized adjustment on client devices. One significant benefit of the approach is that the communication overhead of exchanging large-sized model parameters is reduced and, therefore, improves resource-limited mobile environments. Moreover, another potential solution to the suggested system enhancement suggests implementing large language models into the federated learning systems because large language models have an opportunity to leverage their large pre-trainings and generalization capabilities to address the issue of data scarcity and increase personalization. This remedy however comes at a cost in that new techniques are necessary to interdiscipline the computational demands of large-scale models with privacy guarantees provided by the federated learning in the situation of resource-limited environments. The decrease of the data sparsity and heterogeneity of the client devices which typically leads to diminished model performance in classical federated systems of recommendation is another issue of the field importance. More research on the ability of such models to be effectively tuned to decentralized data and the fact that their privacy processes do not attract the attention of the quality of recommendations and fairness can also be conducted. The Federation Foundation Models development presupposes these issues with the help of collaborative learning in federated structures toward the improved model performance and data privacy as well as the possibility to develop more personalized and context-sen

sitive models. It has the possibility of increasing data and has a smaller computational requirement, with the pre-training and data augmentation techniques, and serves as an option to the problem, such as the shortage of data, variability in computation, etc. More so, federated foundation models offer a robust privacy-preserving scheme to collaboratively fine-tune models with varying disparate and decentralized and non-IID data, combining parameter-efficient and personalization models to decrease the communication and computation expenses. Fine-Tuning of Artificial Intelligence (AI) Foundation Models With Federated Learning, Differential Privacy, Offsite Tuning, and Parameter-Efficient Fine-Tuning (PEFT)\",\"author\":[{\"family\":\"Zhao\",\"given\":\"Jun\"}],\"issued\":{\"date-parts\":[[\"2023\"]]}}}],\"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} Indicatively, with an example, federated adaptation mechanisms can be employed to permit desire -shift variations amidst a user in an agreeable and privacy conscious means with featherweight customized adjustment on client devices. One significant benefit of the approach is that the communication overhead of exchanging large-sized model parameters is reduced and, therefore, improves resource-limited mobile environments. Moreover, another

 potential solution to the suggested system enhancement suggests implementing large language models into th
e federated learning systems because large language models have an opportunity to leverage their large pre-
trainings and generalization capabilities to address the issue of data scarcity and increase personalizatio
n. This remedy however comes at a cost in that new techniques are necessary to interdiscipline the computat
ional demands of large-scale models with privacy guarantees provided by the federated learning in the situa
tion of resource-limited environments. The decrease of the data sparsity and heterogeneity of the client de
vices which typically leads to diminished model performance in classical federated systems of recommendatio
n is another issue of the field importance. More research on the ability of such models to be effectively t
uned to decentralized data and the fact that their privacy processes do not attract the attention of the qu
ality of recommendations and fairness can also be conducted. The Federation Foundation Models development p
resupposes these issues with the help of collaborative learning in federated structures toward the improved
 model performance and data privacy as well as the possibility to develop more personalized and context-sen
sitive models. It has the possibility of increasing data and has a smaller computational requirement, with
the pre-training and data augmentation techniques, and serves as an option to the problem, such as the shor
tage of data, variability in computation, etc. More so, federated foundation models offer a robust privacy-
preserving scheme to collaboratively fine-tune models with varying disparate and decentralized and non-IID
data, combining parameter-efficient and personalization models to decrease the communication and computatio
n expenses. (Abdel-Sater \u0026 Hamza, 2024; Bakhtiari, 2025b; Bandara, 2025; S. Chen, 2024; Z. Jiang et al

"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} Indicatively,
 with an example, federated adaptation mechanisms can be employed to permit desire -shift variations amidst
 a user in an agreeable and privacy conscious means with featherweight customized adjustment on client devi
ces. One significant benefit of the approach is that the communication overhead of exchanging large-sized m
odel parameters is reduced and, therefore, improves resource-limited mobile environments. Moreover, another
 potential solution to the suggested system enhancement suggests implementing large language models into th
e federated learning systems because large language models have an opportunity to leverage their large pre-
trainings and generalization capabilities to address the issue of data scarcity and increase personalizatio
n. This remedy however comes at a cost in that new techniques are necessary to interdiscipline the computat
ional demands of large-scale models with privacy guarantees provided by the federated learning in the situa
tion of resource-limited environments. The decrease of the data sparsity and heterogeneity of the client de
vices which typically leads to diminished model performance in classical federated systems of recommendatio
n is another issue of the field importance. More research on the ability of such models to be effectively t
uned to decentralized data and the fact that their privacy processes do not attract the attention of the qu
ality of recommendations and fairness can also be conducted. The Federation Foundation Models development p
resupposes these issues with the help of collaborative learning in federated structures toward the improved
 model performance and data privacy as well as the possibility to develop more personalized and context-sen
sitive models. It has the possibility of increasing data and has a smaller computational requirement, with
the pre-training and data augmentation techniques, and serves as an option to the problem, such as the shor
tage of data, variability in computation, etc. More so, federated foundation models offer a robust privacy-
preserving scheme to collaboratively fine-tune models with varying disparate and decentralized and non-IID
data, combining parameter-efficient and personalization models to decrease the communication and computatio
n expenses. (Abdel-Sater \u0026 Hamza, 2024; Bakhtiari, 2025b; Bandara, 2025; S. Chen, 2024; Z. Jiang et al

One significant benefit of the approach is that the communication overhead of exchanging large-sized model parameters is reduced and, therefore, improves resource-limited mobile environments. Moreover, another potential solution to the suggested system enhancement suggests implementing large language models into the federated learning systems because large language models have an opportunity to leverage their large pre-trainings and generalization capabilities to address the issue of data scarcity and increase personalization. This remedy however comes at a cost in that new techniques are necessary to interdiscipline the computational demands of large-scale models with privacy guarantees provided by the federated learning in the situation of resource-limited environments. The decrease of the data sparsity and heterogeneity of the client devices which typically leads to diminished model performance in classical federated systems of recommendation is another issue of the field importance. More research on the ability of such models to be effectively tuned to decentralized data and the fact that their privacy processes do not attract the attention of the quality of recommendations and fairness can also be conducted. The Federation Foundation Models development presupposes these issues with the help of collaborative learning in federated structures toward the improved model performance and data privacy as well as the possibility to develop more personalized and context-sensitive models. It has the possibility of increasing data and has a smaller computational requirement, with the pre-training and data augmentation techniques, and serves as an option to the problem, such as the shortage of data, variability in computation, etc. More so, federated foundation models offer a robust privacy-preserving scheme to collaboratively fine-tune models with varying disparate and decentralized and non-IID data, combining parameter-efficient and personalization models to decrease the communication and computation expenses. More research on the ability of such models to be effectively tuned to decentralized data and the fact that their privacy processes do not attract the attention of the quality of recommendations and fairness can also be conducted. The Federation Foundation Models development presupposes these issues with the help of collaborative learning in federated structures toward the improved model performance and data privacy as well as the possibility to develop more personalized and context-sensitive models. It has the possibility of increasing data and has a smaller computational requirement, with the pre-training and data augmentation techniques, and serves as an option to the problem, such as the shortage of data, variability in computation, etc. More so, federated foundation models offer a robust privacy-preserving scheme to collaboratively fine-tune models with varying disparate and decentralized and non-IID data, combining parameter-efficient and personalization models to decrease the communication and computation expenses. One significant benefit of the approach is that the communication overhead of exchanging large-sized model parameters is reduced and, therefore, improves resource-limited mobile environments. Moreover, another potential solution to the suggested system enhancement suggests implementing large language models into the federated learning systems because large language models have an opportunity to leverage their large pre-trainings and generalization capabilities to address the issue of data scarcity and increase personalization. This remedy however comes at a cost in that new techniques are necessary to interdiscipline the computational demands of large-scale models with privacy guarantees provided by the federated learning in the situation of resource-limited environments. The decrease of the data sparsity and heterogeneity of the client devices which typically leads to diminished model performance in classical federated systems of recommendation is another issue of the field importance. More research on the ability of such models to be effectively tuned to decentralized data and the fact that their privacy processes do not attract the attention of the quality of recommendations and fairness can also be conducted. The Federation Foundation Models development presupposes these issues with the help of collaborative learning in federated structures toward the improved model performance and data privacy as well as the possibility to develop more personalized and context-sensitive models. It has the possibility of increasing data and has a smaller computational requirement, with the pre-training and data augmentation techniques, and serves as an option to the problem, such as the shortage of data, variability in computation, etc. More so, federated foundation models offer a robust privacy-preserving scheme to collaboratively fine-tune models with varying disparate and decentralized and non-IID data, combining parameter-efficient and personalization models to decrease the communication and computation expenses. Fine-Tuning of Artificial Intelligence (AI) Foundation Models With Federated Learning, Differential Privacy, Offsite Tuning, and Parameter-Efficient Fine-Tuning (PEFT)\",\"author\":[{\"family\":\"Zhao\",\"given\":\"Jun\"}],\"issued\":{\"date-parts\":[[\"2023\"]]}}}],\"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} Indicatively, with an example, federated adaptation mechanisms can be employed to permit desire -shift variations amidst a user in an agreeable and privacy conscious means with featherweight customized adjustment on client devices. One significant benefit of the approach is that the communication overhead of exchanging large-sized model parameters is reduced and, therefore, improves resource-limited mobile environments. Moreover, another potential solution to the suggested system enhancement suggests implementing large language models into the federated learning systems because large language models have an opportunity to leverage their large pre-trainings and generalization capabilities to address the issue of data scarcity and increase personalization. This remedy however comes at a cost in that new techniques are necessary to interdiscipline the computational demands of large-scale models with privacy guarantees provided by the federated learning in the situation of resource-limited environments. The decrease of the data sparsity and heterogeneity of the client devices which typically leads to diminished model performance in classical federated systems of recommendation is another issue of the field importance. More research on the ability of such models to be effectively tuned to decentralized data and the fact that their privacy processes do not attract the attention of the quality of recommendations and fairness can also be conducted. The Federation Foundation Models development presupposes these issues with the help of collaborative learning in federated structures toward the improved model performance and data privacy as well as the possibility to develop more personalized and context-sensitive models. It has the possibility of increasing data and has a smaller computational requirement, with the pre-training and data augmentation techniques, and serves as an option to the problem, such as the shortage of data, variability in computation, etc. More so, federated foundation models offer a robust privacy-preserving scheme to collaboratively fine-tune models with varying disparate and decentralized and non-IID

data, combining parameter-efficient and personalization models to decrease the communication and computation expenses. (Abdel-Sater \u0026 Hamza, 2024; Bakhtiari, 2025b; Bandara, 2025; S. "schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} Indicatively,
 with an example, federated adaptation mechanisms can be employed to permit desire -shift variations amidst
 a user in an agreeable and privacy conscious means with featherweight customized adjustment on client devi
ces. One significant benefit of the approach is that the communication overhead of exchanging large-sized m
odel parameters is reduced and, therefore, improves resource-limited mobile environments. Moreover, another
 potential solution to the suggested system enhancement suggests implementing large language models into th
e federated learning systems because large language models have an opportunity to leverage their large pre-
trainings and generalization capabilities to address the issue of data scarcity and increase personalizatio
n. This remedy however comes at a cost in that new techniques are necessary to interdiscipline the computat
ional demands of large-scale models with privacy guarantees provided by the federated learning in the situa
tion of resource-limited environments. The decrease of the data sparsity and heterogeneity of the client de
vices which typically leads to diminished model performance in classical federated systems of recommendatio
n is another issue of the field importance. More research on the ability of such models to be effectively t
uned to decentralized data and the fact that their privacy processes do not attract the attention of the qu
ality of recommendations and fairness can also be conducted. The Federation Foundation Models development p
resupposes these issues with the help of collaborative learning in federated structures toward the improved
 model performance and data privacy as well as the possibility to develop more personalized and context-sen
sitive models. It has the possibility of increasing data and has a smaller computational requirement, with
the pre-training and data augmentation techniques, and serves as an option to the problem, such as the shor
tage of data, variability in computation, etc. More so, federated foundation models offer a robust privacy-
preserving scheme to collaboratively fine-tune models with varying disparate and decentralized and non-IID
data, combining parameter-efficient and personalization models to decrease the communication and computatio
n expenses. (Abdel-Sater \u0026 Hamza, 2024; Bakhtiari, 2025b; Bandara, 2025; S. Chen, 2024; Z. Jiang et al

lcers and complications are a significant concern for individuals with diabetes, leading to severe health i
mplications such as lower-limb amputation and reduced quality of life. This chapter discusses applying AI-d
riven personalised offloading device prescriptions as an advanced solution for preventing such conditions.
By harnessing the capabilities of artificial intelligence, this cutting-edge approach enables the prescript
ion of offloading devices tailored to each patient’s specific requirements. This includes the patient’s pre
ferences on offloading devices such as footwear and foot orthotics and their adaptations that suit the pati
ent’s intention of use and lifestyle. Through a series of studies, real-world data analysis and machine lea
rning algorithms, high-risk areas can be identified, facilitating the recommendation of precise offloading
strategies, including custom orthotic insoles, shoe adaptations, or specialised footwear. By including pati
ent-specific factors to promote adherence, proactively addressing pressure points and promoting optimal foo
t mechanics, these personalised offloading devices have the potential to minimise the occurrence of foot ul
cers and associated complications. This chapter proposes an AI-powered Clinical Decision Support System (CD
SS) to recommend personalised prescriptions of offloading devices (footwear and insoles) for patients with
diabetes who are at risk of foot complications. This innovative approach signifies a transformative leap in
 diabetic foot care, offering promising opportunities for preventive healthcare interventions.\",\"containe

a\":{\"id\":781,\"type\":\"article-journal\",\"abstract\":\"With the explosion of delay-sensitive and compu
tation-intensive vehicular applications, traditional cloud computing has encountered enormous challenges. V
ehicular edge computing, as an emerging computing paradigm, has provided powerful support for vehicular net
works. However, vehicle mobility and time-varying characteristics of communication channels have further co
mplicated the design and implementation of vehicular network systems, leading to increased delays and energ
y consumption. To address this problem, this article proposes a hybrid task offloading algorithm that combi
nes deep reinforcement learning with convex optimization algorithms to improve the performance of the algor
ithm. The vehicle’s mobility and common signal-blocking problems in the vehicular edge computing environmen
t are taken into account; to minimize system overhead, firstly, the twin delayed deep deterministic policy
gradient algorithm (TD3) is used for offloading decision-making, with a normalized state space as the input
 to improve convergence efficiency. Then, the Lagrange multiplier method allocates server bandwidth to mult

```
iple users. The simulation results demonstrate that the proposed algorithm surpasses other solutions in ter
ms of delay and energy consumption.\",\"container-title\":\"Electronics\",\"DOI\":\"10.3390/electronics1221

r elaborates on alleviating the energy conservation problem in wireless devices operating under the Interne
t of Things (IoT) environments, by using machine-to-machine (M2M) communication mechanisms. Such IoT wirele
ss terminals, such as wearables, smart glasses, and smart objects, are able to distress energy consumption
 levels of the IoT environments, playing a crucial role to the quality of service (QoS) or quality of experi
ence (QoE) provision for end users under several high demand scenarios, while they are on the move. In this
 context, this paper proposes a new offload-aware recommendation scheme, towards allowing the effective mon
itoring of high energy consumption applications that run in the mobile devices of such IoT ecosystems. The
proposed model enables mobile users having a nonstop provision of on-demand services, while such devices ar
e able to provide the available required resources that are to be exploited in IoT environments. The propos
ed system model and the M2M offloading mechanisms and mathematical foundations, this paper exploits an edge
-based communication mechanism, towards enabling resource-aware recommendation. The performance evaluation
results validate the proposed approach, by assessing the provided model in the framework of the reliability
 provision for the IoT terminals under the use of the recommendation scheme, as well as the energy conserva
tion provision for several mobile devices that are included in the IoT environment during the offloading pr
ocedure.INDEX TERMS Edge computing, energy conservation, IoT offload metrics, offload processing, resource-

\"]]}}}],\"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} Thi
s unification whilst seemingly highly promising presents a number of challenges in specific ways and in pec
uliar details in specifically mobile settings where devices are frequently constrained by low computational
 ability, battery life, storage capacity as well as on and off network, inconsistent connections. All these
 constraints necessitate the development and deployment of highly optimised communication protocols that ca
n be run under variable bandwidth conditions and parameter-efficient fine-tuning controls (minimise memory
footprint and computational overhead) during trainings and inference on devices, One of the key elements in
 this respect is the requirements of memory-efficient recommender systems that can be executed on the lever
aged mobile devices of high-end smartphones to less advanced handsets. To that end, novel techniques of com
pressing the models such as quantisation and pruning are required, which are beneficial in terms of minimiz
ing the size and complexity of the recommendation models without compromising with their predictive capabil
ity. Other problems that make lightweight neural architecture, adaptive offloading schemes and the use of m
odular model components with selective model updating are the problem of cold start in which new users or i
tems have little or no history of interactions information to produce high-value recommendations. (Ahmed et
 al., 2024; Z. Liu et al., 2023; Mavromoustakis et al., 2019)",

lcers and complications are a significant concern for individuals with diabetes, leading to severe health i
mplications such as lower-limb amputation and reduced quality of life. This chapter discusses applying AI-d
riven personalised offloading device prescriptions as an advanced solution for preventing such conditions.
By harnessing the capabilities of artificial intelligence, this cutting-edge approach enables the prescript
ion of offloading devices tailored to each patient’s specific requirements. This includes the patient’s pre
ferences on offloading devices such as footwear and foot orthotics and their adaptations that suit the pati
ent’s intention of use and lifestyle. Through a series of studies, real-world data analysis and machine lea
rning algorithms, high-risk areas can be identified, facilitating the recommendation of precise offloading
strategies, including custom orthotic insoles, shoe adaptations, or specialised footwear. By including pati
ent-specific factors to promote adherence, proactively addressing pressure points and promoting optimal foo
t mechanics, these personalised offloading devices have the potential to minimise the occurrence of foot ul
cers and associated complications. This chapter proposes an AI-powered Clinical Decision Support System (CD
SS) to recommend personalised prescriptions of offloading devices (footwear and insoles) for patients with
diabetes who are at risk of foot complications. This innovative approach signifies a transformative leap in
 diabetic foot care, offering promising opportunities for preventive healthcare interventions.\",\"containe

Approach to Preventing Diabetes-Related Plantar Forefoot Ulcers and Complications\",\"author\":[{\"family\":\"Ahmed\",\"given\":\"Sayed\"},{\"family\":\"Ashad Kabir\",\"given\":\"Muhammad\"},{\"family\":\"E.H. Chowdhury\",\"given\":\"Muhammad\"},{\"family\":\"Nancarrow\",\"given\":\"Susan\"}],\"issued\":{\"date-parts\":[[\"2024\"]]}}},{\"id\":781,\"uris\":[\"http://zotero.org/users/local/M0u71wYg/items/NDZ4AKI2\"],\"itemData\":{\"id\":781,\"type\":\"article-journal\",\"abstract\":\"With the explosion of delay-sensitive and computation-intensive vehicular applications, traditional cloud computing has encountered enormous challenges. Vehicular edge computing, as an emerging computing paradigm, has provided powerful support for vehicular networks. However, vehicle mobility and time-varying characteristics of communication channels have further complicated the design and implementation of vehicular network systems, leading to increased delays and energy consumption. To address this problem, this article proposes a hybrid task offloading algorithm that combines deep reinforcement learning with convex optimization algorithms to improve the performance of the algorithm. The vehicle’s mobility and common signal-blocking problems in the vehicular edge computing environment are taken into account; to minimize system overhead, firstly, the twin delayed deep deterministic policy gradient algorithm (TD3) is used for offloading decision-making, with a normalized state space as the input to improve convergence efficiency. Then, the Lagrange multiplier method allocates server bandwidth to multiple users. The simulation results demonstrate that the proposed algorithm surpasses other solutions in terms of delay and energy consumption.\",\"container-title\":\"Electronics\",\"DOI\":\"10.3390/electronics12214392\",\"issue\":\"21\",\"journalAbbreviation\":\"Electronics\",\"page\":\"4392\",\"title\":\"DRL-Based Hybrid Task Offloading and Resource Allocation in Vehicular Networks\",\"volume\":\"12\",\"author\":[{\"family\":\"Liu\",\"given\":\"Ziang\"},{\"family\":\"Jia\",\"given\":\"Zongpu\"},{\"family\":\"Pang\",\"given\":\"Xiaoyan\"}],\"issued\":{\"date-parts\":[[\"2023\"]]}}},{\"id\":780,\"uris\":[\"http://zotero.org/users/local/M0u71wYg/items/Y2EGH2FC\"],\"itemData\":{\"id\":780,\"type\":\"article-journal\",\"abstract\":\"This paper elaborates on alleviating the energy conservation problem in wireless devices operating under the Internet of Things (IoT) environments, by using machine-to-machine (M2M) communication mechanisms. Such IoT wireless terminals, such as wearables, smart glasses, and smart objects, are able to distress energy consumption levels of the IoT environments, playing a crucial role to the quality of service (QoS) or quality of experience (QoE) provision for end users under several high demand scenarios, while they are on the move. In this context, this paper proposes a new offload-aware recommendation scheme, towards allowing the effective monitoring of high energy consumption applications that run in the mobile devices of such IoT ecosystems. The proposed model enables mobile users having a nonstop provision of on-demand services, while such devices are able to provide the available required resources that are to be exploited in IoT environments. The proposed system model and the M2M offloading mechanisms and mathematical foundations, this paper exploits an edge-based communication mechanism, towards enabling resource-aware recommendation. The performance evaluation results validate the proposed approach, by assessing the provided model in the framework of the reliability provision for the IoT terminals under the use of the recommendation scheme, as well as the energy conservation provision for several mobile devices that are included in the IoT environment during the offloading procedure.INDEX TERMS Edge computing, energy conservation, IoT offload metrics, offload processing, resource-aware recommendation, offload-oriented mobile cloud.\",\"container-title\":\"IEEE Access\",\"DOI\":\"10.1109/access.2019.2931362\",\"journalAbbreviation\":\"IEEE Access\",\"page\":\"102295-102303\",\"title\":\"A Mobile Edge Computing Model Enabling Efficient Computation Offload-Aware Energy Conservation\",\"volume\":\"7\",\"author\":[{\"family\":\"Mavromoustakis\",\"given\":\"Constandinos X.\"},{\"family\":\"Mastorakis\",\"given\":\"George\"},{\"family\":\"Mongay Batalla\",\"given\":\"Jordi\"}],\"issued\":{\"date-parts\":[[\"2019\"]]}}}],\"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} This unification whilst seemingly highly promising presents a number of challenges in specific ways and in peculiar details in specifically mobile settings where devices are frequently constrained by low computational ability, battery life, storage capacity as well as on and off network, inconsistent connections. All these constraints necessitate the development and deployment of highly optimised communication protocols that can be run under variable bandwidth conditions and parameter-efficient fine-tuning controls (minimise memory footprint and computational overhead) during trainings and inference on devices, One of the key elements in this respect is the requirements of memory-efficient recommender systems that can be executed on the leveraged mobile devices of high-end smartphones to less advanced handsets. To that end, novel techniques of compressing the models such as quantisation and pruning are required, which are beneficial in terms of minimizing the size and complexity of the recommendation models without compromising with their predictive capability. Other problems that make lightweight neural architecture, adaptive offloading schemes and the use of modular model components with selective model updating are the problem of cold start in which new users or items have little or no history of interactions information to produce high-value recommendations. This is more so when it comes to federated environments in which data is spread and there are privacy concerns involving the sharing of the data of users. Getting over with this implies that they employ complex techniques, like meta-learning and data enhancement. By modifying models with adaptability to new users or items based on prior knowledge learnt during the execution of a myriad of tasks, meta-learning can help new users or items achieve better generalisation on limited data. The other is data augmentation which artificially creates additional data to be used in training or the effect of current data to be augmented to enhance the learning process to counter the sparsity and augment the robustness of the model. A combination of these methods can allow this system to produce valuable recommendations even in data sparse environments. Moreover, testing of federated recommendation systems in the mobile environment should move beyond the conventional metrics of accuracy to include testing of privacy leakage, communication cost and system utility as a whole. This is composed in the formulation of successful methods of measurement to the extent to which privacy preserving methods including privacy and secure aggregation, safeguard the privacy of individual user data to the cost of subtracting the performance of suggestions obtained. In practice, this is typically a very fine balancing act because on one hand, the provision of increased privacy by the means of noise, cryptographic or other tools may compromise the quality or expressiven

ess of the model and on the other end, greater respect towards the utility might also increase the cost of
privacy of the systems - the architectural design of federated learning systems in mobile recommendation sy
stems is therefore a matter of significant concern to balance these trade-offs. The main points are provisi
on of combination of adaptive privacy budgets, dynamic aggregation techniques by considering device heterog
eneity and incentives to produce client sustained participation. More importantly, the system must uphold t
he abilities of the effectiveness personalisation where the desirability of recommendations is not subdivid
ed when the constraints of the occurrence of local computation and privacy regulations are incorporated wit
hin consideration. The trade-offs involved and ensuring that this balance is paramount to real-world implem
entation because this has a direct effect to user trust, engagement and overall adoption of federated learn
ing based mobile recommendation services. in short, even though the combination of federated learning and r
ecommender systems in mobile setting has a lot of a potential in preserving privacy of the user personalisa
tion, it also demands the radical solutions to the problem of resource limitation, cold starting and the in
terrelation between privacy and utility. To deal with these problems, highly developed model design, optimi
sation strategies and integrated evaluation structures are necessary in order to make the most out of poten
tial of this beneficial paradigm and to reveal its full potential in practical scenarios. (Abdollahi, 2023;

"PPBRFL: Privacy-Preserving Byzantine-Robust Federated Learning\",\"author\":[{\"family\":\"Zhou\",\"given\
":\"Qun\"}],\"issued\":{\"date-parts\":[[\"2024\"]]}}}],\"schema\":\"https://github.com/citation-style-lang
uage/schema/raw/master/csl-citation.json\"} This is more so when it comes to federated environments in whic
h data is spread and there are privacy concerns involving the sharing of the data of users. Getting over wi
th this implies that they employ complex techniques, like meta-learning and data enhancement. By modifying
models with adaptability to new users or items based on prior knowledge learnt during the execution of a my
riad of tasks, meta-learning can help new users or items achieve better generalisation on limited data. The
 other is data augmentation which artificially creates additional data to be used in training or the effect
 of current data to be augmented to enhance the learning process to counter the sparsity and augment the ro
bustness of the model. A combination of these methods can allow this system to produce valuable recommendat
ions even in data sparse environments. Moreover, testing of federated recommendation systems in the mobile
environment should move beyond the conventional metrics of accuracy to include testing of privacy leakage,
communication cost and system utility as a whole. This is composed in the formulation of successful methods
 of measurement to the extent to which privacy preserving methods including privacy and secure aggregation,
 safeguard the privacy of individual user data to the cost of subtracting the performance of suggestions ob
tained. In practice, this is typically a very fine balancing act because on one hand, the provision of incr
eased privacy by the means of noise, cryptographic or other tools may compromise the quality or expressiven
ess of the model and on the other end, greater respect towards the utility might also increase the cost of
privacy of the systems - the architectural design of federated learning systems in mobile recommendation sy
stems is therefore a matter of significant concern to balance these trade-offs. The main points are provisi
on of combination of adaptive privacy budgets, dynamic aggregation techniques by considering device heterog
eneity and incentives to produce client sustained participation. More importantly, the system must uphold t
he abilities of the effectiveness personalisation where the desirability of recommendations is not subdivid
ed when the constraints of the occurrence of local computation and privacy regulations are incorporated wit
hin consideration. The trade-offs involved and ensuring that this balance is paramount to real-world implem
entation because this has a direct effect to user trust, engagement and overall adoption of federated learn
ing based mobile recommendation services. in short, even though the combination of federated learning and r
ecommender systems in mobile setting has a lot of a potential in preserving privacy of the user personalisa
tion, it also demands the radical solutions to the problem of resource limitation, cold starting and the in
terrelation between privacy and utility. To deal with these problems, highly developed model design, optimi
sation strategies and integrated evaluation structures are necessary in order to make the most out of poten
tial of this beneficial paradigm and to reveal its full potential in practical scenarios. (Abdollahi, 2023;

"PPBRFL: Privacy-Preserving Byzantine-Robust Federated Learning\",\"author\":[{\"family\":\"Zhou\",\"given\
":\"Qun\"}],\"issued\":{\"date-parts\":[[\"2024\"]]}}}],\"schema\":\"https://github.com/citation-style-lang
uage/schema/raw/master/csl-citation.json\"} This is more so when it comes to federated environments in which data is spread and there are privacy concerns involving the sharing of the data of users. Getting over with this implies that they employ complex techniques, like meta-learning and data enhancement. By modifying models with adaptability to new users or items based on prior knowledge learnt during the execution of a myriad of tasks, meta-learning can help new users or items achieve better generalisation on limited data. The other is data augmentation which artificially creates additional data to be used in training or the effect of current data to be augmented to enhance the learning process to counter the sparsity and augment the robustness of the model. A combination of these methods can allow this system to produce valuable recommendations even in data sparse environments. Moreover, testing of federated recommendation systems in the mobile environment should move beyond the conventional metrics of accuracy to include testing of privacy leakage, communication cost and system utility as a whole. This is composed in the formulation of successful methods of measurement to the extent to which privacy preserving methods including privacy and secure aggregation, safeguard the privacy of individual user data to the cost of subtracting the performance of suggestions obtained. In practice, this is typically a very fine balancing act because on one hand, the provision of increased privacy by the means of noise, cryptographic or other tools may compromise the quality or expressiven

```
ess of the model and on the other end, greater respect towards the utility might also increase the cost of
privacy of the systems - the architectural design of federated learning systems in mobile recommendation sy
stems is therefore a matter of significant concern to balance these trade-offs. The main points are provisi
on of combination of adaptive privacy budgets, dynamic aggregation techniques by considering device heterog
eneity and incentives to produce client sustained participation. More importantly, the system must uphold t
he abilities of the effectiveness personalisation where the desirability of recommendations is not subdivid
ed when the constraints of the occurrence of local computation and privacy regulations are incorporated wit
hin consideration. The trade-offs involved and ensuring that this balance is paramount to real-world implem
entation because this has a direct effect to user trust, engagement and overall adoption of federated learn
ing based mobile recommendation services. in short, even though the combination of federated learning and r
ecommender systems in mobile setting has a lot of a potential in preserving privacy of the user personalisa
tion, it also demands the radical solutions to the problem of resource limitation, cold starting and the in
terrelation between privacy and utility. To deal with these problems, highly developed model design, optimi
sation strategies and integrated evaluation structures are necessary in order to make the most out of poten
tial of this beneficial paradigm and to reveal its full potential in practical scenarios. (Abdollahi, 2023;

"PPBRFL: Privacy-Preserving Byzantine-Robust Federated Learning\",\"author\":[{\"family\":\"Zhou\",\"given\
":\"Qun\"}],\"issued\":{\"date-parts\":[[\"2024\"]]}}}],\"schema\":\"https://github.com/citation-style-lang
uage/schema/raw/master/csl-citation.json\"} This is more so when it comes to federated environments in whic
h data is spread and there are privacy concerns involving the sharing of the data of users. Getting over wi
th this implies that they employ complex techniques, like meta-learning and data enhancement. By modifying 
models with adaptability to new users or items based on prior knowledge learnt during the execution of a my
riad of tasks, meta-learning can help new users or items achieve better generalisation on limited data. The
 other is data augmentation which artificially creates additional data to be used in training or the effect
 of current data to be augmented to enhance the learning process to counter the sparsity and augment the ro
bustness of the model. A combination of these methods can allow this system to produce valuable recommendat
ions even in data sparse environments. Moreover, testing of federated recommendation systems in the mobile 
environment should move beyond the conventional metrics of accuracy to include testing of privacy leakage, 
communication cost and system utility as a whole. This is composed in the formulation of successful methods
 of measurement to the extent to which privacy preserving methods including privacy and secure aggregation,
 safeguard the privacy of individual user data to the cost of subtracting the performance of suggestions ob
tained. In practice, this is typically a very fine balancing act because on one hand, the provision of incr
eased privacy by the means of noise, cryptographic or other tools may compromise the quality or expressiven
ess of the model and on the other end, greater respect towards the utility might also increase the cost of 
privacy of the systems - the architectural design of federated learning systems in mobile recommendation sy
stems is therefore a matter of significant concern to balance these trade-offs. The main points are provisi
on of combination of adaptive privacy budgets, dynamic aggregation techniques by considering device heterog
eneity and incentives to produce client sustained participation. More importantly, the system must uphold t
he abilities of the effectiveness personalisation where the desirability of recommendations is not subdivid
ed when the constraints of the occurrence of local computation and privacy regulations are incorporated wit
hin consideration. The trade-offs involved and ensuring that this balance is paramount to real-world implem
entation because this has a direct effect to user trust, engagement and overall adoption of federated learn
ing based mobile recommendation services. in short, even though the combination of federated learning and r
ecommender systems in mobile setting has a lot of a potential in preserving privacy of the user personalisa
tion, it also demands the radical solutions to the problem of resource limitation, cold starting and the in
terrelation between privacy and utility. To deal with these problems, highly developed model design, optimi
sation strategies and integrated evaluation structures are necessary in order to make the most out of poten
tial of this beneficial paradigm and to reveal its full potential in practical scenarios. (Abdollahi, 2023;

"PPBRFL: Privacy-Preserving Byzantine-Robust Federated Learning\",\"author\":[{\"family\":\"Zhou\",\"given\
":\"Qun\"}],\"issued\":{\"date-parts\":[[\"2024\"]]}}}],\"schema\":\"https://github.com/citation-style-lang
uage/schema/raw/master/csl-citation.json\"} This is more so when it comes to federated environments in whic
h data is spread and there are privacy concerns involving the sharing of the data of users. Getting over wi
th this implies that they employ complex techniques, like meta-learning and data enhancement. By modifying
models with adaptability to new users or items based on prior knowledge learnt during the execution of a my
riad of tasks, meta-learning can help new users or items achieve better generalisation on limited data. The
 other is data augmentation which artificially creates additional data to be used in training or the effect
 of current data to be augmented to enhance the learning process to counter the sparsity and augment the ro
bustness of the model. A combination of these methods can allow this system to produce valuable recommendat
ions even in data sparse environments. Moreover, testing of federated recommendation systems in the mobile
environment should move beyond the conventional metrics of accuracy to include testing of privacy leakage,
communication cost and system utility as a whole. This is composed in the formulation of successful methods
 of measurement to the extent to which privacy preserving methods including privacy and secure aggregation,
 safeguard the privacy of individual user data to the cost of subtracting the performance of suggestions ob

```
tained. In practice, this is typically a very fine balancing act because on one hand, the provision of incr
eased privacy by the means of noise, cryptographic or other tools may compromise the quality or expressiven
ess of the model and on the other end, greater respect towards the utility might also increase the cost of 
privacy of the systems - the architectural design of federated learning systems in mobile recommendation sy
stems is therefore a matter of significant concern to balance these trade-offs. The main points are provisi
on of combination of adaptive privacy budgets, dynamic aggregation techniques by considering device heterog
eneity and incentives to produce client sustained participation. More importantly, the system must uphold t
he abilities of the effectiveness personalisation where the desirability of recommendations is not subdivid
ed when the constraints of the occurrence of local computation and privacy regulations are incorporated wit
hin consideration. The trade-offs involved and ensuring that this balance is paramount to real-world implem
entation because this has a direct effect to user trust, engagement and overall adoption of federated learn
ing based mobile recommendation services. in short, even though the combination of federated learning and r
ecommender systems in mobile setting has a lot of a potential in preserving privacy of the user personalisa
tion, it also demands the radical solutions to the problem of resource limitation, cold starting and the in
terrelation between privacy and utility. To deal with these problems, highly developed model design, optimi
sation strategies and integrated evaluation structures are necessary in order to make the most out of poten
tial of this beneficial paradigm and to reveal its full potential in practical scenarios. (Abdollahi, 2023;

Getting over with this implies that they employ complex techniques, like meta-learning and data enhancement. By modifying models with adaptability to new users or items based on prior knowledge learnt during the execution of a myriad of tasks, meta-learning can help new users or items achieve better generalisation on limited data. The other is data augmentation which artificially creates additional data to be used in training or the effect of current data to be augmented to enhance the learning process to counter the sparsity and augment the robustness of the model. A combination of these methods can allow this system to produce valuable recommendations even in data sparse environments. Moreover, testing of federated recommendation systems in the mobile environment should move beyond the conventional metrics of accuracy to include testing of privacy leakage, communication cost and system utility as a whole. This is composed in the formulation of successful methods of measurement to the extent to which privacy preserving methods including privacy and secure aggregation, safeguard the privacy of individual user data to the cost of subtracting the performance of suggestions obtained. In practice, this is typically a very fine balancing act because on one hand, the provision of increased privacy by the means of noise, cryptographic or other tools may compromise the quality or expressiveness of the model and on the other end, greater respect towards the utility might also increase the cost of privacy of the systems - the architectural design of federated learning systems in mobile recommendation systems is therefore a matter of significant concern to balance these trade-offs. The main points are provision of combination of adaptive privacy budgets, dynamic aggregation techniques by considering device heterogeneity and incentives to produce client sustained participation. More importantly, the system must uphold the abilities of the effectiveness personalisation where the desirability of recommendations is not subdivided when the constraints of the occurrence of local computation and privacy regulations are incorporated within consideration. The trade-offs involved and ensuring that this balance is paramount to real-world implementation because this has a direct effect to user trust, engagement and overall adoption of federated learning based mobile recommendation services. in short, even though the combination of federated learning and recommender systems in mobile setting has a lot of a potential in preserving privacy of the user personalisation, it also demands the radical solutions to the problem of resource limitation, cold starting and the interrelation between privacy and utility. To deal with these problems, highly developed model design, optimisation strategies and integrated evaluation structures are necessary in order to make the most out of potential of this beneficial paradigm and to reveal its full potential in practical scenarios. "PPBRFL: Privacy-Preserving Byzantine-Robust Federated Learning\",\"author\":[{\"family\":\"Zhou\",\"given\
":\"Qun\"}],\"issued\":{\"date-parts\":[[\"2024\"]]}}}],\"schema\":\"https://github.com/citation-style-lang
uage/schema/raw/master/csl-citation.json\"} This is more so when it comes to federated environments in whic
h data is spread and there are privacy concerns involving the sharing of the data of users. Getting over wi
th this implies that they employ complex techniques, like meta-learning and data enhancement. By modifying
models with adaptability to new users or items based on prior knowledge learnt during the execution of a my
riad of tasks, meta-learning can help new users or items achieve better generalisation on limited data. The
 other is data augmentation which artificially creates additional data to be used in training or the effect
 of current data to be augmented to enhance the learning process to counter the sparsity and augment the ro
bustness of the model. A combination of these methods can allow this system to produce valuable recommendat
ions even in data sparse environments. Moreover, testing of federated recommendation systems in the mobile
environment should move beyond the conventional metrics of accuracy to include testing of privacy leakage,
communication cost and system utility as a whole. This is composed in the formulation of successful methods
 of measurement to the extent to which privacy preserving methods including privacy and secure aggregation,
 safeguard the privacy of individual user data to the cost of subtracting the performance of suggestions ob
tained. In practice, this is typically a very fine balancing act because on one hand, the provision of incr
eased privacy by the means of noise, cryptographic or other tools may compromise the quality or expressiven
ess of the model and on the other end, greater respect towards the utility might also increase the cost of
privacy of the systems - the architectural design of federated learning systems in mobile recommendation sy
stems is therefore a matter of significant concern to balance these trade-offs. The main points are provisi
on of combination of adaptive privacy budgets, dynamic aggregation techniques by considering device heterog
eneity and incentives to produce client sustained participation. More importantly, the system must uphold t
he abilities of the effectiveness personalisation where the desirability of recommendations is not subdivid
ed when the constraints of the occurrence of local computation and privacy regulations are incorporated wit
hin consideration. The trade-offs involved and ensuring that this balance is paramount to real-world implem
entation because this has a direct effect to user trust, engagement and overall adoption of federated learn
ing based mobile recommendation services. in short, even though the combination of federated learning and r
ecommender systems in mobile setting has a lot of a potential in preserving privacy of the user personalisa
tion, it also demands the radical solutions to the problem of resource limitation, cold starting and the in
terrelation between privacy and utility. To deal with these problems, highly developed model design, optimi
sation strategies and integrated evaluation structures are necessary in order to make the most out of poten
tial of this beneficial paradigm and to reveal its full potential in practical scenarios. (Abdollahi, 2023;

uage/schema/raw/master/csl-citation.json\"} This is more so when it comes to federated environments in which data is spread and there are privacy concerns involving the sharing of the data of users. Getting over with this implies that they employ complex techniques, like meta-learning and data enhancement. By modifying models with adaptability to new users or items based on prior knowledge learnt during the execution of a myriad of tasks, meta-learning can help new users or items achieve better generalisation on limited data. The other is data augmentation which artificially creates additional data to be used in training or the effect of current data to be augmented to enhance the learning process to counter the sparsity and augment the robustness of the model. A combination of these methods can allow this system to produce valuable recommendations even in data sparse environments. Moreover, testing of federated recommendation systems in the mobile environment should move beyond the conventional metrics of accuracy to include testing of privacy leakage, communication cost and system utility as a whole. This is composed in the formulation of successful methods of measurement to the extent to which privacy preserving methods including privacy and secure aggregation,

safeguard the privacy of individual user data to the cost of subtracting the performance of suggestions ob
tained. In practice, this is typically a very fine balancing act because on one hand, the provision of incr
eased privacy by the means of noise, cryptographic or other tools may compromise the quality or expressiven
ess of the model and on the other end, greater respect towards the utility might also increase the cost of
privacy of the systems - the architectural design of federated learning systems in mobile recommendation sy
stems is therefore a matter of significant concern to balance these trade-offs. The main points are provisi
on of combination of adaptive privacy budgets, dynamic aggregation techniques by considering device heterog
eneity and incentives to produce client sustained participation. More importantly, the system must uphold t
he abilities of the effectiveness personalisation where the desirability of recommendations is not subdivid
ed when the constraints of the occurrence of local computation and privacy regulations are incorporated wit
hin consideration. The trade-offs involved and ensuring that this balance is paramount to real-world implem
entation because this has a direct effect to user trust, engagement and overall adoption of federated learn
ing based mobile recommendation services. in short, even though the combination of federated learning and r
ecommender systems in mobile setting has a lot of a potential in preserving privacy of the user personalisa
tion, it also demands the radical solutions to the problem of resource limitation, cold starting and the in
terrelation between privacy and utility. To deal with these problems, highly developed model design, optimi
sation strategies and integrated evaluation structures are necessary in order to make the most out of poten
tial of this beneficial paradigm and to reveal its full potential in practical scenarios. (Abdollahi, 2023;

"PPBRFL: Privacy-Preserving Byzantine-Robust Federated Learning\",\"author\":[{\"family\":\"Zhou\",\"given\
":\"Qun\"}],\"issued\":{\"date-parts\":[[\"2024\"]]}}}],\"schema\":\"https://github.com/citation-style-lang
uage/schema/raw/master/csl-citation.json\"} This is more so when it comes to federated environments in whic
h data is spread and there are privacy concerns involving the sharing of the data of users. Getting over wi
th this implies that they employ complex techniques, like meta-learning and data enhancement. By modifying 
models with adaptability to new users or items based on prior knowledge learnt during the execution of a my
riad of tasks, meta-learning can help new users or items achieve better generalisation on limited data. The
 other is data augmentation which artificially creates additional data to be used in training or the effect
 of current data to be augmented to enhance the learning process to counter the sparsity and augment the ro
bustness of the model. A combination of these methods can allow this system to produce valuable recommendat
ions even in data sparse environments. Moreover, testing of federated recommendation systems in the mobile 
environment should move beyond the conventional metrics of accuracy to include testing of privacy leakage, 
communication cost and system utility as a whole. This is composed in the formulation of successful methods
 of measurement to the extent to which privacy preserving methods including privacy and secure aggregation,
 safeguard the privacy of individual user data to the cost of subtracting the performance of suggestions ob
tained. In practice, this is typically a very fine balancing act because on one hand, the provision of incr
eased privacy by the means of noise, cryptographic or other tools may compromise the quality or expressiven
ess of the model and on the other end, greater respect towards the utility might also increase the cost of 
privacy of the systems - the architectural design of federated learning systems in mobile recommendation sy
stems is therefore a matter of significant concern to balance these trade-offs. The main points are provisi
on of combination of adaptive privacy budgets, dynamic aggregation techniques by considering device heterog
eneity and incentives to produce client sustained participation. More importantly, the system must uphold t
he abilities of the effectiveness personalisation where the desirability of recommendations is not subdivid
ed when the constraints of the occurrence of local computation and privacy regulations are incorporated wit
hin consideration. The trade-offs involved and ensuring that this balance is paramount to real-world implem
entation because this has a direct effect to user trust, engagement and overall adoption of federated learn
ing based mobile recommendation services. in short, even though the combination of federated learning and r
ecommender systems in mobile setting has a lot of a potential in preserving privacy of the user personalisa
tion, it also demands the radical solutions to the problem of resource limitation, cold starting and the in
terrelation between privacy and utility. To deal with these problems, highly developed model design, optimi
sation strategies and integrated evaluation structures are necessary in order to make the most out of poten
tial of this beneficial paradigm and to reveal its full potential in practical scenarios. (Abdollahi, 2023;

Learning\",\"author\":[{\"family\":\"Zhou\",\"given\":\"Qun\"}],\"issued\":{\"date-parts\":[[\"2024\"]]}}}],\"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} This is more so when it comes to federated environments in which data is spread and there are privacy concerns involving the sharing of the data of users. Getting over with this implies that they employ complex techniques, like meta-learning and data enhancement. By modifying models with adaptability to new users or items based on prior knowledge learnt during the execution of a myriad of tasks, meta-learning can help new users or items achieve better generalisation on limited data. The other is data augmentation which artificially creates additional data to be used in training or the effect of current data to be augmented to enhance the learning process to counter the sparsity and augment the robustness of the model. A combination of these methods can allow this system to produce valuable recommendations even in data sparse environments. Moreover, testing of federated recommendation systems in the mobile environment should move beyond the conventional metrics of accuracy to include testing of privacy leakage, communication cost and system utility as a whole. This is composed in the formulation of successful methods of measurement to the extent to which privacy preserving methods including privacy and secure aggregation, safeguard the privacy of individual user data to the cost of subtracting the performance of suggestions ob

```
tained. In practice, this is typically a very fine balancing act because on one hand, the provision of incr
eased privacy by the means of noise, cryptographic or other tools may compromise the quality or expressiven
ess of the model and on the other end, greater respect towards the utility might also increase the cost of 
privacy of the systems - the architectural design of federated learning systems in mobile recommendation sy
stems is therefore a matter of significant concern to balance these trade-offs. The main points are provisi
on of combination of adaptive privacy budgets, dynamic aggregation techniques by considering device heterog
eneity and incentives to produce client sustained participation. More importantly, the system must uphold t
he abilities of the effectiveness personalisation where the desirability of recommendations is not subdivid
ed when the constraints of the occurrence of local computation and privacy regulations are incorporated wit
hin consideration. The trade-offs involved and ensuring that this balance is paramount to real-world implem
entation because this has a direct effect to user trust, engagement and overall adoption of federated learn
ing based mobile recommendation services. in short, even though the combination of federated learning and r
ecommender systems in mobile setting has a lot of a potential in preserving privacy of the user personalisa
tion, it also demands the radical solutions to the problem of resource limitation, cold starting and the in
terrelation between privacy and utility. To deal with these problems, highly developed model design, optimi
sation strategies and integrated evaluation structures are necessary in order to make the most out of poten
tial of this beneficial paradigm and to reveal its full potential in practical scenarios. (Abdollahi, 2023;

"PPBRFL: Privacy-Preserving Byzantine-Robust Federated Learning\",\"author\":[{\"family\":\"Zhou\",\"given\
":\"Qun\"}],\"issued\":{\"date-parts\":[[\"2024\"]]}}}],\"schema\":\"https://github.com/citation-style-lang
uage/schema/raw/master/csl-citation.json\"} This is more so when it comes to federated environments in whic
h data is spread and there are privacy concerns involving the sharing of the data of users. Getting over wi
th this implies that they employ complex techniques, like meta-learning and data enhancement. By modifying
models with adaptability to new users or items based on prior knowledge learnt during the execution of a my
riad of tasks, meta-learning can help new users or items achieve better generalisation on limited data. The
 other is data augmentation which artificially creates additional data to be used in training or the effect
 of current data to be augmented to enhance the learning process to counter the sparsity and augment the ro
bustness of the model. A combination of these methods can allow this system to produce valuable recommendat
ions even in data sparse environments. Moreover, testing of federated recommendation systems in the mobile
environment should move beyond the conventional metrics of accuracy to include testing of privacy leakage,
communication cost and system utility as a whole. This is composed in the formulation of successful methods
 of measurement to the extent to which privacy preserving methods including privacy and secure aggregation,
 safeguard the privacy of individual user data to the cost of subtracting the performance of suggestions ob

tained. In practice, this is typically a very fine balancing act because on one hand, the provision of incr
eased privacy by the means of noise, cryptographic or other tools may compromise the quality or expressiven
ess of the model and on the other end, greater respect towards the utility might also increase the cost of
privacy of the systems - the architectural design of federated learning systems in mobile recommendation sy
stems is therefore a matter of significant concern to balance these trade-offs. The main points are provisi
on of combination of adaptive privacy budgets, dynamic aggregation techniques by considering device heterog
eneity and incentives to produce client sustained participation. More importantly, the system must uphold t
he abilities of the effectiveness personalisation where the desirability of recommendations is not subdivid
ed when the constraints of the occurrence of local computation and privacy regulations are incorporated wit
hin consideration. The trade-offs involved and ensuring that this balance is paramount to real-world implem
entation because this has a direct effect to user trust, engagement and overall adoption of federated learn
ing based mobile recommendation services. in short, even though the combination of federated learning and r
ecommender systems in mobile setting has a lot of a potential in preserving privacy of the user personalisa
tion, it also demands the radical solutions to the problem of resource limitation, cold starting and the in
terrelation between privacy and utility. To deal with these problems, highly developed model design, optimi
sation strategies and integrated evaluation structures are necessary in order to make the most out of poten
tial of this beneficial paradigm and to reveal its full potential in practical scenarios. (Abdollahi, 2023;

Getting over with this implies that they employ complex techniques, like meta-learning and data enhancement. By modifying models with adaptability to new users or items based on prior knowledge learnt during the execution of a myriad of tasks, meta-learning can help new users or items achieve better generalisation on limited data. The other is data augmentation which artificially creates additional data to be used in training or the effect of current data to be augmented to enhance the learning process to counter the sparsity and augment the robustness of the model. A combination of these methods can allow this system to produce valuable recommendations even in data sparse environments. Moreover, testing of federated recommendation systems in the mobile environment should move beyond the conventional metrics of accuracy to include testing of privacy leakage, communication cost and system utility as a whole. This is composed in the formulation of successful methods of measurement to the extent to which privacy preserving methods including privacy and secure aggregation, safeguard the privacy of individual user data to the cost of subtracting the performance of suggestions obtained. In practice, this is typically a very fine balancing act because on one hand, the provision of increased privacy by the means of noise, cryptographic or other tools may compromise the quality or expressiveness of the model and on the other end, greater respect towards the utility might also increase the cost of privacy of the systems - the architectural design of federated learning systems in mobile recommendation systems is therefore a matter of significant concern to balance these trade-offs. The main points are provision of combination of adaptive privacy budgets, dynamic aggregation techniques by considering device heterogeneity and incentives to produce client sustained participation. More importantly, the system must uphold the abilities of the effectiveness personalisation where the desirability of recommendations is not subdivided when the constraints of the occurrence of local computation and privacy regulations are incorporated within consideration. The trade-offs involved and ensuring that this balance is paramount to real-world implementation because this has a direct effect to user trust, engagement and overall adoption of federated learning based mobile recommendation services. in short, even though the combination of federated learning and recommender systems in mobile setting has a lot of a potential in preserving privacy of the user personalisation, it also demands the radical solutions to the problem of resource limitation, cold starting and the interrelation between privacy and utility. To deal with these problems, highly developed model design, optimisation strategies and integrated evaluation structures are necessary in order to make the most out of potential of this beneficial paradigm and to reveal its full potential in practical scenarios. "PPBRFL: Privacy-Preserving Byzantine-Robust Federated Learning\",\"author\":[{\"family\":\"Zhou\",\"given\
":\"Qun\"}],\"issued\":{\"date-parts\":[[\"2024\"]]}}}],\"schema\":\"https://github.com/citation-style-lang
uage/schema/raw/master/csl-citation.json\"} This is more so when it comes to federated environments in whic
h data is spread and there are privacy concerns involving the sharing of the data of users. Getting over wi
th this implies that they employ complex techniques, like meta-learning and data enhancement. By modifying
models with adaptability to new users or items based on prior knowledge learnt during the execution of a my
riad of tasks, meta-learning can help new users or items achieve better generalisation on limited data. The
 other is data augmentation which artificially creates additional data to be used in training or the effect
 of current data to be augmented to enhance the learning process to counter the sparsity and augment the ro
bustness of the model. A combination of these methods can allow this system to produce valuable recommendat
ions even in data sparse environments. Moreover, testing of federated recommendation systems in the mobile
environment should move beyond the conventional metrics of accuracy to include testing of privacy leakage,
communication cost and system utility as a whole. This is composed in the formulation of successful methods
 of measurement to the extent to which privacy preserving methods including privacy and secure aggregation,
 safeguard the privacy of individual user data to the cost of subtracting the performance of suggestions ob
tained. In practice, this is typically a very fine balancing act because on one hand, the provision of incr
eased privacy by the means of noise, cryptographic or other tools may compromise the quality or expressiven
ess of the model and on the other end, greater respect towards the utility might also increase the cost of
privacy of the systems - the architectural design of federated learning systems in mobile recommendation sy
stems is therefore a matter of significant concern to balance these trade-offs. The main points are provisi
on of combination of adaptive privacy budgets, dynamic aggregation techniques by considering device heterog
eneity and incentives to produce client sustained participation. More importantly, the system must uphold t
he abilities of the effectiveness personalisation where the desirability of recommendations is not subdivid
ed when the constraints of the occurrence of local computation and privacy regulations are incorporated wit
hin consideration. The trade-offs involved and ensuring that this balance is paramount to real-world implem
entation because this has a direct effect to user trust, engagement and overall adoption of federated learn
ing based mobile recommendation services. in short, even though the combination of federated learning and r
ecommender systems in mobile setting has a lot of a potential in preserving privacy of the user personalisa
tion, it also demands the radical solutions to the problem of resource limitation, cold starting and the in
terrelation between privacy and utility. To deal with these problems, highly developed model design, optimi
sation strategies and integrated evaluation structures are necessary in order to make the most out of poten
tial of this beneficial paradigm and to reveal its full potential in practical scenarios. (Abdollahi, 2023;

Getting over with this implies that they employ complex techniques, like meta-learning and data enhancement. By modifying models with adaptability to new users or items based on prior knowledge learnt during the execution of a myriad of tasks, meta-learning can help new users or items achieve better generalisation on limited data. The other is data augmentation which artificially creates additional data to be used in training or the effect of current data to be augmented to enhance the learning process to counter the sparsity and augment the robustness of the model. A combination of these methods can allow this system to produce valuable recommendations even in data sparse environments. Moreover, testing of federated recommendation systems in the mobile environment should move beyond the conventional metrics of accuracy to include testing of privacy leakage, communication cost and system utility as a whole. This is composed in the formulation of successful methods of measurement to the extent to which privacy preserving methods including privacy and secure aggregation, safeguard the privacy of individual user data to the cost of subtracting the performance of suggestions obtained. In practice, this is typically a very fine balancing act because on one hand, the provision of increased privacy by the means of noise, cryptographic or other tools may compromise the quality or expressiveness of the model and on the other end, greater respect towards the utility might also increase the cost of privacy of the systems - the architectural design of federated learning systems in mobile recommendation systems is therefore a matter of significant concern to balance these trade-offs. The main points are provision of combination of adaptive privacy budgets, dynamic aggregation techniques by considering device heterogeneity and incentives to produce client sustained participation. More importantly, the system must uphold the abilities of the effectiveness personalisation where the desirability of recommendations is not subdivided when the constraints of the occurrence of local computation and privacy regulations are incorporated within consideration. The trade-offs involved and ensuring that this balance is paramount to real-world implementation because this has a direct effect to user trust, engagement and overall adoption of federated learning based mobile recommendation services. in short, even though the combination of federated learning and recommender systems in mobile setting has a lot of a potential in preserving privacy of the user personalisation, it also demands the radical solutions to the problem of resource limitation, cold starting and the interrelation between privacy and utility. To deal with these problems, highly developed model design, optimisation strategies and integrated evaluation structures are necessary in order to make the most out of potential of this beneficial paradigm and to reveal its full potential in practical scenarios. "PPBRFL: Privacy-Preserving Byzantine-Robust Federated Learning\",\"author\":[{\"family\":\"Zhou\",\"given\
":\"Qun\"}],\"issued\":{\"date-parts\":[[\"2024\"]]}}}],\"schema\":\"https://github.com/citation-style-lang
uage/schema/raw/master/csl-citation.json\"} This is more so when it comes to federated environments in which data is spread and there are privacy concerns involving the sharing of the data of users. Getting over with this implies that they employ complex techniques, like meta-learning and data enhancement. By modifying models with adaptability to new users or items based on prior knowledge learnt during the execution of a myriad of tasks, meta-learning can help new users or items achieve better generalisation on limited data. The other is data augmentation which artificially creates additional data to be used in training or the effect

 of current data to be augmented to enhance the learning process to counter the sparsity and augment the ro
bustness of the model. A combination of these methods can allow this system to produce valuable recommendat
ions even in data sparse environments. Moreover, testing of federated recommendation systems in the mobile
environment should move beyond the conventional metrics of accuracy to include testing of privacy leakage,
communication cost and system utility as a whole. This is composed in the formulation of successful methods
 of measurement to the extent to which privacy preserving methods including privacy and secure aggregation,
 safeguard the privacy of individual user data to the cost of subtracting the performance of suggestions ob
tained. In practice, this is typically a very fine balancing act because on one hand, the provision of incr
eased privacy by the means of noise, cryptographic or other tools may compromise the quality or expressiven
ess of the model and on the other end, greater respect towards the utility might also increase the cost of
privacy of the systems - the architectural design of federated learning systems in mobile recommendation sy
stems is therefore a matter of significant concern to balance these trade-offs. The main points are provisi
on of combination of adaptive privacy budgets, dynamic aggregation techniques by considering device heterog
eneity and incentives to produce client sustained participation. More importantly, the system must uphold t
he abilities of the effectiveness personalisation where the desirability of recommendations is not subdivid
ed when the constraints of the occurrence of local computation and privacy regulations are incorporated wit
hin consideration. The trade-offs involved and ensuring that this balance is paramount to real-world implem
entation because this has a direct effect to user trust, engagement and overall adoption of federated learn
ing based mobile recommendation services. in short, even though the combination of federated learning and r
ecommender systems in mobile setting has a lot of a potential in preserving privacy of the user personalisa
tion, it also demands the radical solutions to the problem of resource limitation, cold starting and the in
terrelation between privacy and utility. To deal with these problems, highly developed model design, optimi
sation strategies and integrated evaluation structures are necessary in order to make the most out of poten
tial of this beneficial paradigm and to reveal its full potential in practical scenarios. (Abdollahi, 2023;

Moreover, testing of federated recommendation systems in the mobile environment should move beyond the conventional metrics of accuracy to include testing of privacy leakage, communication cost and system utility as a whole. This is composed in the formulation of successful methods of measurement to the extent to which privacy preserving methods including privacy and secure aggregation, safeguard the privacy of individual user data to the cost of subtracting the performance of suggestions obtained. In practice, this is typically a very fine balancing act because on one hand, the provision of increased privacy by the means of noise, cryptographic or other tools may compromise the quality or expressiveness of the model and on the other end, greater respect towards the utility might also increase the cost of privacy of the systems - the architectural design of federated learning systems in mobile recommendation systems is therefore a matter of significant concern to balance these trade-offs. The main points are provision of combination of adaptive privacy budgets, dynamic aggregation techniques by considering device heterogeneity and incentives to produce client sustained participation. More importantly, the system must uphold the abilities of the effectiveness personalisation where the desirability of recommendations is not subdivided when the constraints of the occurrence of local computation and privacy regulations are incorporated within consideration. The trade-offs involved and ensuring that this balance is paramount to real-world implementation because this has a direct effect to user trust, engagement and overall adoption of federated learning based mobile recommendation services. in short, even though the combination of federated learning and recommender systems in mobile setting has a lot of a potential in preserving privacy of the user personalisation, it also demands the radical solutions to the problem of resource limitation, cold starting and the interrelation between privacy and utility. To deal with these problems, highly developed model design, optimisation strategies and integrated evaluation structures are necessary in order to make the most out of potential of this beneficial paradigm and to reveal its full potential in practical scenarios. Getting over with this implies that they employ complex techniques, like meta-learning and data enhancement. By modifying models with adaptability to new users or items based on prior knowledge learnt during the execution of a myriad of tasks, meta-learning can help new users or items achieve better generalisation on limited data. The other is data augmentation which artificially creates additional data to be used in training or the effect of current data to be augmented to enhance the learning process to counter the sparsity and augment the robustness of the model. A combination of these methods can allow this system to produce valuable recommendations even in data sparse environments. Moreover, testing of federated recommendation systems in the mobile environment should move beyond the conventional metrics of accuracy to include testing of privacy leakage, communication cost and system utility as a whole. This is composed in the formulation of successful methods of measurement to the extent to which privacy preserving methods including privacy and secure aggregation, safeguard the privacy of individual user data to the cost of subtracting the performance of suggestions obtained. In practice, this is typically a very fine balancing act because on one hand, the provision of increased privacy by the means of noise, cryptographic or other tools may compromise the quality or expressiveness of the model and on the other end, greater respect towards the utility might also increase the cost of privacy of the systems - the architectural design of federated learning systems in mobile recommendation systems is therefore a matter of significant concern to balance these trade-offs. The main points are provision of combination of adaptive privacy budgets, dynamic aggregation techniques by considering device heterogeneity and incentives to produce client sustained participation. More importantly, the system must uphold the abilities of the effectiveness personalisation where the desirability of recommendations is not subdivided when the constraints of the occurrence of local computation and privacy regulations are incorporated within consideration. This is more so when it comes to federated environments in which data is spread and there are privacy concerns involving the sharing of the data of users. Getting over with this implies that they employ complex techniques, like meta-learning and data enhancement. By modifying models with adaptability to new users or items based on prior knowledge learnt during the execution of a myriad of tasks, meta-learning can help new users or items achieve better generalisation on limited data. The other is data augmentation which artificially creates additional data to be used in training or the effect of current data to be augmented to enhance the learning process to counter the sparsity and augment the robustness of the model. A combination of these methods can allow this system to produce valuable recommendations even in data sparse environments. Moreover, testing of federated recommendation systems in the mobile environment should move beyond the conventional metrics of accuracy to include testing of privacy leakage, communication cost and system utility as a whole. This is composed in the formulation of successful methods

```
 of measurement to the extent to which privacy preserving methods including privacy and secure aggregation,
 safeguard the privacy of individual user data to the cost of subtracting the performance of suggestions ob
tained. In practice, this is typically a very fine balancing act because on one hand, the provision of incr
eased privacy by the means of noise, cryptographic or other tools may compromise the quality or expressiven
ess of the model and on the other end, greater respect towards the utility might also increase the cost of 
privacy of the systems - the architectural design of federated learning systems in mobile recommendation sy
stems is therefore a matter of significant concern to balance these trade-offs. The main points are provisi
on of combination of adaptive privacy budgets, dynamic aggregation techniques by considering device heterog
eneity and incentives to produce client sustained participation. More importantly, the system must uphold t
he abilities of the effectiveness personalisation where the desirability of recommendations is not subdivid
ed when the constraints of the occurrence of local computation and privacy regulations are incorporated wit
hin consideration. The trade-offs involved and ensuring that this balance is paramount to real-world implem
entation because this has a direct effect to user trust, engagement and overall adoption of federated learn
ing based mobile recommendation services. in short, even though the combination of federated learning and r
ecommender systems in mobile setting has a lot of a potential in preserving privacy of the user personalisa
tion, it also demands the radical solutions to the problem of resource limitation, cold starting and the in
terrelation between privacy and utility. To deal with these problems, highly developed model design, optimi
sation strategies and integrated evaluation structures are necessary in order to make the most out of poten
tial of this beneficial paradigm and to reveal its full potential in practical scenarios. (Abdollahi, 2023;

It enables the model to take advantage of abundant semantic representations and inductive biases held in the foundation model and also learn to make recommendations to every user individually. Such a tradeoff is so important in federated recommendation systems, where one can suit very well to the needs of a specific user, without the overall intelligences that the foundation model represents. Second, regularization term enhances a successful knowledge transfer through ensuring

that the difference between the fine-tuned parameters and the foundation model is controlled. It enables th
e model to take advantage of abundant semantic representations and inductive biases held in the foundation
model and also learn to make recommendations to every user individually. Such a tradeoff is so important in
 federated recommendation systems, where one can suit very well to the needs of a specific user, without th
e overall intelligences that the foundation model represents. (Feng et al., 2022; A. Gupta et al., 2019; Q.

Second, regularization term enhances a successful knowledge transfer through ensuring that the difference between the fine-tuned parameters and the foundation model is controlled. It enables the model to take advantage of abundant semantic representations and inductive biases held in the foundation model and also learn to make recommendations to every user individually. Such a tradeoff is so important in federated recommendation systems, where one can suit very well to the needs of a specific user, without the overall intelligences that the foundation model represents. csl-citation.json\"} Second, regularization term enhances a successful knowledge transfer through ensuring
that the difference between the fine-tuned parameters and the foundation model is controlled. It enables th
e model to take advantage of abundant semantic representations and inductive biases held in the foundation
model and also learn to make recommendations to every user individually. Such a tradeoff is so important in
 federated recommendation systems, where one can suit very well to the needs of a specific user, without th
e overall intelligences that the foundation model represents. (Feng et al., 2022; A. Gupta et al., 2019; Q.

Second, regularization term enhances a successful knowledge transfer through ensuring that the difference between the fine-tuned parameters and the foundation model is controlled. It enables the model to take advantage of abundant semantic representations and inductive biases held in the foundation model and also learn to make recommendations to every user individually. Such a tradeoff is so important in federated recommendation systems, where one can suit very well to the needs of a specific user, without the overall intelligences that the foundation model represents. csl-citation.json\"} Second, regularization term enhances a successful knowledge transfer through ensuring
that the difference between the fine-tuned parameters and the foundation model is controlled. It enables th
e model to take advantage of abundant semantic representations and inductive biases held in the foundation
model and also learn to make recommendations to every user individually. Such a tradeoff is so important in
 federated recommendation systems, where one can suit very well to the needs of a specific user, without th
e overall intelligences that the foundation model represents. (Feng et al., 2022; A. Gupta et al., 2019; Q.

Second, regularization term enhances a successful knowledge transfer through ensuring that the difference between the fine-tuned parameters and the foundation model is controlled. It enables the model to take advantage of abundant semantic representations and inductive biases held in the foundation model and also learn to make recommendations to every user individually. Such a tradeoff is so important in federated recommendation systems, where one can suit very well to the needs of a specific user, without the overall intelligences that the foundation model represents. "schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} The way out o
f this is an interesting solution introduced by the highly learned foundation models with high-level semant
ic knowledge that can be utilized to generate good representations of users and items and thus allows zero-
shot and few-shot learning to simplify the process. The capacity is accompanied by the necessity of providi
ng an adequate transfer of knowledge within the framework of a basis model, which are being loaded into the
 federated learning environment without subjecting it to a heavy consumption of computationally intensive l
oad. The foundation of web adapt on mobile federated learning is also elaborated to incorporate a balancing
 of the model structure and training algorithms to be executed using hardcore budgets of resources. It will
 involve the creation of new solutions in order to quantize and prune optimized to execute on-device infere
nce and federated learning approaches that are able to assist the capabilities of different hardware settin
gs and network circumstances. Such a complicated interaction implies that both the architectural aspects of
 the foundation models and the limitations of communication of federated mobile environments should be shar
ed broadly to achieve the right accuracy privacy trade-offs. Further bonus plans to attract clients and eff
ective deployment strategies are great in the environmentally friendly platform of the federated foundation
 model on the wireless field. Speaking more specifically, by using the foundation models and the system of
federated learning, we will be capable of performing a more personalized approach and an efficient system o
f recommendations, by dealing with such concerns as the data sparsity and non-IID distributions of data amo
ng the consumers. However, with the integration, new complexities are attached including an effective perso
nalization modelling because of the variety of preferences of the separated clients and effective fusion be
tween collective knowledge of previously trained foundation models and personalization of the users. These
complexities lead to issues, and these issues are best addressed by a complex resolution, which is normally
 a trade-off between the computation problems of large models and privacy protecting on-device learning and
 efficient knowledge transfer relations in a federated scheme. These methods are usually parameter efficien
t fine-tuning methods, which can be adapted to the specifics of the individual user, without necessarily do
ing considerable customization to the large ground model itself. It is a paradigm of teacher-student learni

```
ng that can be effectively deployed to small devices that belong to clients to utilize the amount of knowle
dge about the domain of the enormous foundation model. It is a method that is often supported with methods 
such as knowledge distillation applied in the student model in order to realize causally similar performanc
e with reduced computation costs as opposed to a larger teacher model. It also can be potentially useful in
 a mobile environment when the computing resources present is minimal; in this case one can have a recommen
dation system that possesses high capability at levels that do not necessarily overload the available capac
ity of the device. Besides, parameter-efficient fine-tuning approaches, which can be suggested to supplemen
t quantization approaches like AWQ, can also become a potential solution to running and training these larg
e models on federated networks, which can tackle the technicalities related to the on-device execution. The
 mechanism is additionally effective as it reduces communication overheads in terms of reducing the amount 
of data that is transmitted between clients and central server which in turn increases the practicability o
f executing more compilated recommender systems in the background of mobile that has bandwidth limitation. 
The federated learning models could be enhanced by adding the foundation models to help improve collaborati
ve filtering through exploiting the immense inductive biases and external knowledge exemplified in FMs and 
that has been acquired by examining many massive datasets to provide guidance to more common adaptable comp
onents of the recommendation system. Not only in making good initial recommendation is it addressing the pr
oblem of cold-start, but also in addressing the problem of data sparsity and heterogeneity of distributed m
obile dataset. (Carreira-Perpiñán, 2017; Y. Cheng, 2024; Z. Deng, 2022; Dhaouadi et al., 2025; Duan \u0026

The capacity is accompanied by the necessity of providing an adequate transfer of knowledge within the framework of a basis model, which are being loaded into the federated learning environment without subjecting it to a heavy consumption of computationally intensive load. The foundation of web adapt on mobile federated learning is also elaborated to incorporate a balancing of the model structure and training algorithms to be executed using hardcore budgets of resources. It will involve the creation of new solutions in order to quantize and prune optimized to execute on-device inference and federated learning approaches that are able to assist the capabilities of different hardware settings and network circumstances. Such a complicated interaction implies that both the architectural aspects of the foundation models and the limitations of communication of federated mobile environments should be shared broadly to achieve the right accuracy privacy trade-offs. Further bonus plans to attract clients and effective deployment strategies are great in the environmentally friendly platform of the federated foundation model on the wireless field. Speaking more specifically, by using the foundation models and the system of federated learning, we will be capable of performing a more personalized approach and an efficient system of recommendations, by dealing with such concerns as the data sparsity and non-IID distributions of data among the consumers. However, with the integration, new complexities are attached including an effective personalization modelling because of the variety of preferences of the separated clients and effective fusion between collective knowledge of previously trained foundation models and personalization of the users. These complexities lead to issues, and these issues are best addressed by a complex resolution, which is normally a trade-off between the computation problems of large models and privacy protecting on-device learning and efficient knowledge transfer relations in a federated scheme. These methods are usually parameter efficient fine-tuning methods, which can be adapted to the specifics of the individual user, without necessarily doing considerable customization to the large ground model itself. It is a paradigm of teacher-student learning that can be effectively deployed to small devices that belong to clients to utilize the amount of knowledge about the domain of the enormous foundation model. It is a method that is often supported with methods such as knowledge distillation applied in the student model in order to realize causally similar performance with reduced computation costs as opposed to a larger teacher model. It also can be potentially useful in a mobile environment when the computing resources present is minimal; in this case one can have a recommendation system that possesses high capability at levels that do not necessarily overload the available capacity of the device. Besides, parameter-efficient fine-tuning approaches, which can be suggested to supplement quantization approaches like AWQ, can also become a potential solution to running and training these large models on federated networks, which can tackle the technicalities related to the on-device execution. The mechanism is additionally effective as it reduces communication overheads in terms of reducing the amount of data that is transmitted between clients and central server which in turn increases the practicability of executing more compilated recommender systems in the background of mobile that has bandwidth limitation. The federated learning models could be enhanced by adding the foundation models to help improve collaborative filtering through exploiting the immense inductive biases and external knowledge exemplified in FMs and that has been acquired by examining many massive datasets to provide guidance to more common adaptable components of the recommendation system. Not only in making good initial recommendation is it addressing the problem of cold-start, but also in addressing the problem of data sparsity and heterogeneity of distributed mobile dataset. The capacity is accompanied by the necessity of providing an adequate transfer of knowledge within the framework of a basis model, which are being loaded into the federated learning environment without subjecting it to a heavy consumption of computationally intensive load. The foundation of web adapt on mobile federated learning is also elaborated to incorporate a balancing of the model structure and training algorithms to be executed using hardcore budgets of resources. It will involve the creation of new solutions in order to quantize and prune optimized to execute on-device inference and federated learning approaches that are able to assist the capabilities of different hardware settings and network circumstances. Such a complicated interaction implies that both the architectural aspects of the foundation models and the limitations of communication of federated mobile environments should be shared broadly to achieve the right accuracy privacy trade-offs. Further bonus plans to attract clients and effective deployment strategies are great in the environmentally friendly platform of the federated foundation model on the wireless field. Speaking more specifically, by using the foundation models and the system of federated learning, we will be capable of performing a more personalized approach and an efficient system of recommendations, by dealing with such concerns as the data sparsity and non-IID distributions of data among the consumers. However, with the integration, new complexities are attached including an effective personalization modelling because of the variety of preferences of the separated clients and effective fusion between collective knowledge of previously trained foundation models and personalization of the users. These complexities lead to issues, and these issues are best addressed by a complex resolution, which is normally a trade-off between the computation problems of large models and privacy protecting on-device learning and efficient knowledge transfer relations in a federated scheme. These methods are usually parameter efficient fine-tuning methods, which can be adapted to the specifics of the individual user, without necessarily doing considerable customization to the large ground model itself. It is a paradigm of teacher-student learning that can be effectively deployed to small devices that belong to clients to utilize the amount of knowledge about the domain of the enormous foundation model. It is a method that is often supported with methods such as knowledge distillation applied in the student model in order to realize causally similar performance with reduced computation costs as opposed to a larger teacher model. It also can be potentially useful in a mobile environment when the computing resources present is minimal; in this case one can have a recommendation system that possesses high capability at levels that do not necessarily overload the available capacity of the device. Besides, parameter-efficient fine-tuning approaches, which can be suggested to supplemen

t quantization approaches like AWQ, can also become a potential solution to running and training these large models on federated networks, which can tackle the technicalities related to the on-device execution. The mechanism is additionally effective as it reduces communication overheads in terms of reducing the amount of data that is transmitted between clients and central server which in turn increases the practicability of executing more compilated recommender systems in the background of mobile that has bandwidth limitation. The federated learning models could be enhanced by adding the foundation models to help improve collaborative filtering through exploiting the immense inductive biases and external knowledge exemplified in FMs and that has been acquired by examining many massive datasets to provide guidance to more common adaptable components of the recommendation system. Not only in making good initial recommendation is it addressing the problem of cold-start, but also in addressing the problem of data sparsity and heterogeneity of distributed mobile dataset. ",\"title\":\"Deep Hybrid Compression Network for Lidar Point Cloud Classification and Segmentation\",\"author\":[{\"family\":\"Zhao\",\"given\":\"Zhi\"},{\"family\":\"Ma\",\"given\":\"Yanxin\"},{\"family\":\"Xu\",\"given\":\"Ke\"},{\"family\":\"Wan\",\"given\":\"Jianwei\"}],\"issued\":{\"date-parts\":[[\"2023\"]]}}}],\"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} The way out of this is an interesting solution introduced by the highly learned foundation models with high-level semantic knowledge that can be utilized to generate good representations of users and items and thus allows zero-shot and few-shot learning to simplify the process. The capacity is accompanied by the necessity of providing an adequate transfer of knowledge within the framework of a basis model, which are being loaded into the federated learning environment without subjecting it to a heavy consumption of computationally intensive load. The foundation of web adapt on mobile federated learning is also elaborated to incorporate a balancing of the model structure and training algorithms to be executed using hardcore budgets of resources. It will involve the creation of new solutions in order to quantize and prune optimized to execute on-device inference and federated learning approaches that are able to assist the capabilities of different hardware settings and network circumstances. Such a complicated interaction implies that both the architectural aspects of the foundation models and the limitations of communication of federated mobile environments should be shared broadly to achieve the right accuracy privacy trade-offs. Further bonus plans to attract clients and effective deployment strategies are great in the environmentally friendly platform of the federated foundation model on the wireless field. Speaking more specifically, by using the foundation models and the system of federated learning, we will be capable of performing a more personalized approach and an efficient system of recommendations, by dealing with such concerns as the data sparsity and non-IID distributions of data among the consumers. However, with the integration, new complexities are attached including an effective personalization modelling because of the variety of preferences of the separated clients and effective fusion between collective knowledge of previously trained foundation models and personalization of the users. These complexities lead to issues, and these issues are best addressed by a complex resolution, which is normally a trade-off between the computation problems of large models and privacy protecting on-device learning and efficient knowledge transfer relations in a federated scheme. These methods are usually parameter efficient fine-tuning methods, which can be adapted to the specifics of the individual user, without necessarily doing considerable customization to the large ground model itself. It is a paradigm of teacher-student learning that can be effectively deployed to small devices that belong to clients to utilize the amount of knowledge about the domain of the enormous foundation model. It is a method that is often supported with methods such as knowledge distillation applied in the student model in order to realize causally similar performance with reduced computation costs as opposed to a larger teacher model. It also can be potentially useful in a mobile environment when the computing resources present is minimal; in this case one can have a recommendation system that possesses high capability at levels that do not necessarily overload the available capacity of the device. Besides, parameter-efficient fine-tuning approaches, which can be suggested to supplement quantization approaches like AWQ, can also become a potential solution to running and training these large models on federated networks, which can tackle the technicalities related to the on-device execution. The mechanism is additionally effective as it reduces communication overheads in terms of reducing the amount of data that is transmitted between clients and central server which in turn increases the practicability of executing more compilated recommender systems in the background of mobile that has bandwidth limitation. The federated learning models could be enhanced by adding the foundation models to help improve collaborative filtering through exploiting the immense inductive biases and external knowledge exemplified in FMs and that has been acquired by examining many massive datasets to provide guidance to more common adaptable components of the recommendation system. Not only in making good initial recommendation is it addressing the problem of cold-start, but also in addressing the problem of data sparsity and heterogeneity of distributed mobile dataset.
