"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} A specific re
levance of this adaptive approach is specifically considering the fact that representatives of the opposite
 side may capitalize on weaknesses in order to make an esoteric set of attacks, such as membership inferenc
e and gradient leaks, and in the process, to provoke the shortcomings of the currently available privacy-en
hancing technologies. It is thus essential that in future studies, efforts be made to strictly test federat
ed foundation models concerning the emerging threats, such as evasion methods that have the capability of s
pecifically targeting large language models, to ensure that federated foundation models are secure and resi
lient in practical applications. (S. Ali et al., 2025; Aljanabi et al., 2024; Alruwaili et al., 2024; Amich

"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} A specific re
levance of this adaptive approach is specifically considering the fact that representatives of the opposite
 side may capitalize on weaknesses in order to make an esoteric set of attacks, such as membership inferenc
e and gradient leaks, and in the process, to provoke the shortcomings of the currently available privacy-en
hancing technologies. It is thus essential that in future studies, efforts be made to strictly test federat
ed foundation models concerning the emerging threats, such as evasion methods that have the capability of s
pecifically targeting large language models, to ensure that federated foundation models are secure and resi
lient in practical applications. (S. Ali et al., 2025; Aljanabi et al., 2024; Alruwaili et al., 2024; Amich

It is thus essential that in future studies, efforts be made to strictly test federated foundation models concerning the emerging threats, such as evasion methods that have the capability of specifically targeting large language models, to ensure that federated foundation models are secure and resilient in practical applications. "schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} A specific re
levance of this adaptive approach is specifically considering the fact that representatives of the opposite
 side may capitalize on weaknesses in order to make an esoteric set of attacks, such as membership inferenc
e and gradient leaks, and in the process, to provoke the shortcomings of the currently available privacy-en
hancing technologies. It is thus essential that in future studies, efforts be made to strictly test federat
ed foundation models concerning the emerging threats, such as evasion methods that have the capability of s
pecifically targeting large language models, to ensure that federated foundation models are secure and resi
lient in practical applications. (S. Ali et al., 2025; Aljanabi et al., 2024; Alruwaili et al., 2024; Amich

"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} A specific re
levance of this adaptive approach is specifically considering the fact that representatives of the opposite
 side may capitalize on weaknesses in order to make an esoteric set of attacks, such as membership inferenc
e and gradient leaks, and in the process, to provoke the shortcomings of the currently available privacy-en
hancing technologies. It is thus essential that in future studies, efforts be made to strictly test federat
ed foundation models concerning the emerging threats, such as evasion methods that have the capability of s
pecifically targeting large language models, to ensure that federated foundation models are secure and resi
lient in practical applications. (S. Ali et al., 2025; Aljanabi et al., 2024; Alruwaili et al., 2024; Amich

"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} A specific re
levance of this adaptive approach is specifically considering the fact that representatives of the opposite
 side may capitalize on weaknesses in order to make an esoteric set of attacks, such as membership inferenc
e and gradient leaks, and in the process, to provoke the shortcomings of the currently available privacy-en
hancing technologies. It is thus essential that in future studies, efforts be made to strictly test federat
ed foundation models concerning the emerging threats, such as evasion methods that have the capability of s
pecifically targeting large language models, to ensure that federated foundation models are secure and resi
lient in practical applications. (S. Ali et al., 2025; Aljanabi et al., 2024; Alruwaili et al., 2024; Amich

"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} A specific re
levance of this adaptive approach is specifically considering the fact that representatives of the opposite
 side may capitalize on weaknesses in order to make an esoteric set of attacks, such as membership inferenc
e and gradient leaks, and in the process, to provoke the shortcomings of the currently available privacy-en
hancing technologies. It is thus essential that in future studies, efforts be made to strictly test federat
ed foundation models concerning the emerging threats, such as evasion methods that have the capability of s
pecifically targeting large language models, to ensure that federated foundation models are secure and resi
lient in practical applications. (S. Ali et al., 2025; Aljanabi et al., 2024; Alruwaili et al., 2024; Amich

ts\":[[\"2025\"]]}}}],\"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citatio
n.json\"} One major field where the challenge is enormous is the clinical AI. In the clinical AI, It is hig
hly Essential to hide the data And secure the data by adding noise An insured that privacy is intact as as
high as possible. However, because of the trade off When too much noise is added to hide the data, the inac
curacy in the recommendations increases rapidly. Sometimes the inaccuracy goes over the roof, so much so th
at the recommendations become useless. Now, second problem is that if the clinical data and the recommendat
ions of the clinical data are to be displayed on mobile system, because the mobile system are computational
ly weaker than any other system for example Laptop or desktop, decoding of the hidden data becomes even dif
ficult. Devices like mobile phones prove almost useless in decoding the hidden data for the clinical AI Due
 to their computationally weak nature. It has to be thought about the fact that any privacy mechanism we em
ploy, especially on mobile recommendation systems along with other platforms like your hosting server etc.
has to be created dynamic in nature. Which means that if a recommendation system is being recommended on mo
bile phone, it is different from the one that is being recommended on a hosting website. This is because th
e nature of threats and attacks keep changing from time to time. Similar is the case with data distribution
. For example, in the field of medical science, new diseases keep coming in. New devices are launched that
may have completely different hardware and computational power, so that the privacy mechanism that worked o
n previous versions of the device may prove null and void in its purpose when employed in this newly launch
ed device. This situation may put us into a situation where we are fighting with old disease with old techn
ologies and privacy mechanism, while the new more powerful disease comes up and does damage even more rapid
ly than any disease we previously encountered with our older privacy protection mechanisms. Then again, the
 problem that comes is to find a balance between protecting the data using privacy mechanism and the accura
cy which the recommendation system as a consequence shows to the users in their device. The problem gets bi
gger and severe in more complex machine learning models like speech recognition and medical image analysis,
 where this balance between privacy and accuracy, if biased towards privacy, will result in even severely i
naccurate recommended contents. For example, in speech recognition, if we add more noise to train the syste
m with strong privacy, this extra noise when sent out to work in real environment where user will speak wo
rds and sentences for the machine to listen to and interpret will result in wrong words being interpreted b
y the system. This will make the system useless for daily communication and usage. Similarly, if we apply a
 similar noisy machine learning model (i.e. A model trend on too much noisy data for privacy protection),
The final result when employee to real life medical applications may cause the model to miss critical featu
res in X ray or CT scan or completely false positive reports. And even worse is that missing out on feature
s in the images which point towards underlying disease may result in false negatives and the patient may be
 advised to not take any serious action. (Ahluwalia, 2021; Almsallat, 2025; Batista, 2025; Graham \u0026 Ha

In the clinical AI, It is highly Essential to hide the data And secure the data by adding noise An insured that privacy is intact as as high as possible. However, because of the trade off When too much noise is added to hide the data, the inaccuracy in the recommendations increases rapidly. Sometimes the inaccuracy goes over the roof, so much so that the recommendations become useless. Now, second problem is that if the clinical data and the recommendations of the clinical data are to be displayed on mobile system, because the mobile system are computationally weaker than any other system for example Laptop or desktop, decoding of the hidden data becomes even difficult. Devices like mobile phones prove almost useless in decoding the hidden data for the clinical AI Due to their computationally weak nature. It has to be thought about the fact that any privacy mechanism we employ, especially on mobile recommendation systems along with other platforms like your hosting server etc. has to be created dynamic in nature. Which means that if a recommendation system is being recommended on mobile phone, it is different from the one that is being recommended on a hosting website. This is because the nature of threats and attacks keep changing from time to time. Similar is the case with data distribution. For example, in the field of medical science, new diseases keep coming in. New devices are launched that may have completely different hardware and computational power, so that the privacy mechanism that worked on previous versions of the device may prove null and void in its purpose when employed in this newly launched device. This situation may put us into a situation where we are fighting with old disease with old technologies and privacy mechanism, while the new more powerful disease comes up and does damage even more rapidly than any disease we previously encountered with our older privacy protection mechanisms. Then again, the problem that comes is to find a balance between protecting the data using privacy mechanism and the accuracy which the recommendation system as a consequence shows to the users in their device. The problem gets bigger and severe in more complex machine learning models like speech recognition and medical image analysis, where this balance between privacy and accuracy, if biased towards privacy, will result in even severely inaccurate recommended contents. For example, in speech recognition, if we add more noise to train the system with strong privacy, this extra noise when sent out to work in real environment where user will speak words and sentences for the machine to listen to and interpret will result in wrong words being interpreted by the system. This will make the system useless for daily communication and usage. Similarly, if we apply a similar noisy machine learning model (i.e. A model trend on too much noisy data for privacy protection), The final result when employee to real life medical applications may cause the model to miss critical features in X ray or CT scan or completely false positive reports. And even worse is that missing out on features in the images which point towards underlying disease may result in false negatives and the patient may be advised to not take any serious action. In the clinical AI, It is highly Essential to hide the data And secure the data by adding noise An insured that privacy is intact as as high as possible. However, because of the trade off When too much noise is added to hide the data, the inaccuracy in the recommendations increases rapidly. Sometimes the inaccuracy goes over the roof, so much so that the recommendations become useless. Now, second problem is that if the clinical data and the recommendations of the clinical data are to be displayed on mobile system, because the mobile system are computationally weaker than any other system for example Laptop or desktop, decoding of the hidden data becomes even difficult. Devices like mobile phones prove almost useless in decoding the hidden data for the clinical AI Due to their computationally weak nature. It has to be thought about the fact that any privacy mechanism we employ, especially on mobile recommendation systems along with other platforms like your hosting server etc. has to be created dynamic in nature. Which means that if a recommendation system is being recommended on mobile phone, it is different from the one that is being recommended on a hosting website. This is because the nature of threats and attacks keep changing from time to time. Similar is the case with data distribution. For example, in the field of medical science, new diseases keep coming in. New devices are launched that may have completely different hardware and computational power, so that the privacy mechanism that worked on previous versions of the device may prove null and void in its purpose when employed in this newly launched device. This situation may put us into a situation where we are fighting with old disease with old technologies and privacy mechanism, while the new more powerful disease comes up and does damage even more rapidly than any disease we previously encountered with our older privacy protection mechanisms. Then again, the problem that comes is to find a balance between protecting the data using privacy mechanism and the accuracy which the recommendation system as a consequence shows to the users in their device. The problem gets bigger and severe in more complex machine learning models like speech recognition and medical image analysis, where this balance between privacy and accuracy, if biased towards privacy, will result in even severely inaccurate recommended contents. For example, in speech recognition, if we add more noise to train the system with strong privacy, this extra noise when sent out to work in real environment where user will speak wo

rds and sentences for the machine to listen to and interpret will result in wrong words being interpreted by the system. This will make the system useless for daily communication and usage. Similarly, if we apply a similar noisy machine learning model (i.e. A model trend on too much noisy data for privacy protection), The final result when employee to real life medical applications may cause the model to miss critical features in X ray or CT scan or completely false positive reports. And even worse is that missing out on features in the images which point towards underlying disease may result in false negatives and the patient may be advised to not take any serious action. \"itemData\":{\"id\":1129,\"type\":\"article-journal\",\"container-title\":\"Open Information and Computer Integrated Technologies\",\"DOI\":\"10.32620/oikit.2025.105.19\",\"title\":\"[redacted]\
",\"author\":[{\"family\":\"[redacted]\",\"given\":\"[redacted]\"}],\"issued\":{\"date-parts\":[[\"2025\"]]}}}],\"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} One major field where the challenge is enormous is the clinical AI. In the clinical AI, It is highly Essential to hide the data And secure the data by adding noise An insured that privacy is intact as as high as possible. However, because of the trade off When too much noise is added to hide the data, the inaccuracy in the recommendations increases rapidly. Sometimes the inaccuracy goes over the roof, so much so that the recommendations become useless. Now, second problem is that if the clinical data and the recommendations of the clinical data are to be displayed on mobile system, because the mobile system are computationally weaker than any other system for example Laptop or desktop, decoding of the hidden data becomes even difficult. Devices like mobile phones prove almost useless in decoding the hidden data for the clinical AI Due to their computationally weak nature. It has to be thought about the fact that any privacy mechanism we employ, especially on mobile recommendation systems along with other platforms like your hosting server etc. has to be created dynamic in nature. Which means that if a recommendation system is being recommended on mobile phone, it is different from the one that is being recommended on a hosting website. This is because the nature of threats and attacks keep changing from time to time. Similar is the case with data distribution. For example, in the field of medical science, new diseases keep coming in. New devices are launched that may have completely different hardware and computational power, so that the privacy mechanism that worked on previous versions of the device may prove null and void in its purpose when employed in this newly launched device. This situation may put us into a situation where we are fighting with old disease with old technologies and privacy mechanism, while the new more powerful disease comes up and does damage even more rapidly than any disease we previously encountered with our older privacy protection mechanisms. Then again, the problem that comes is to find a balance between protecting the data using privacy mechanism and the accuracy which the recommendation system as a consequence shows to the users in their device. The problem gets bigger and severe in more complex machine learning models like speech recognition and medical image analysis, where this balance between privacy and accuracy, if biased towards privacy, will result in even severely inaccurate recommended contents. For example, in speech recognition, if we add more noise to train the system with strong privacy, this extra noise when sent out to work in real environment where user will speak words and sentences for the machine to listen to and interpret will result in wrong words being interpreted by the system. This will make the system useless for daily communication and usage. Similarly, if we apply a similar noisy machine learning model (i.e. A model trend on too much noisy data for privacy protection), The final result when employee to real life medical applications may cause the model to miss critical features in X ray or CT scan or completely false positive reports. And even worse is that missing out on features in the images which point towards underlying disease may result in false negatives and the patient may be advised to not take any serious action. n.json\"} One major field where the challenge is enormous is the clinical AI. In the clinical AI, It is hig
hly Essential to hide the data And secure the data by adding noise An insured that privacy is intact as as
high as possible. However, because of the trade off When too much noise is added to hide the data, the inac
curacy in the recommendations increases rapidly. Sometimes the inaccuracy goes over the roof, so much so th
at the recommendations become useless. Now, second problem is that if the clinical data and the recommendat
ions of the clinical data are to be displayed on mobile system, because the mobile system are computational
ly weaker than any other system for example Laptop or desktop, decoding of the hidden data becomes even dif
ficult. Devices like mobile phones prove almost useless in decoding the hidden data for the clinical AI Due
 to their computationally weak nature. It has to be thought about the fact that any privacy mechanism we em
ploy, especially on mobile recommendation systems along with other platforms like your hosting server etc.
has to be created dynamic in nature. Which means that if a recommendation system is being recommended on mo
bile phone, it is different from the one that is being recommended on a hosting website. This is because th
e nature of threats and attacks keep changing from time to time. Similar is the case with data distribution
. For example, in the field of medical science, new diseases keep coming in. New devices are launched that
may have completely different hardware and computational power, so that the privacy mechanism that worked o
n previous versions of the device may prove null and void in its purpose when employed in this newly launch
ed device. This situation may put us into a situation where we are fighting with old disease with old techn
ologies and privacy mechanism, while the new more powerful disease comes up and does damage even more rapid
ly than any disease we previously encountered with our older privacy protection mechanisms. Then again, the
 problem that comes is to find a balance between protecting the data using privacy mechanism and the accura
cy which the recommendation system as a consequence shows to the users in their device. The problem gets bi
gger and severe in more complex machine learning models like speech recognition and medical image analysis,
 where this balance between privacy and accuracy, if biased towards privacy, will result in even severely i
naccurate recommended contents. For example, in speech recognition, if we add more noise to train the syste
m with strong  privacy, this extra noise when sent out to work in real environment where user will speak wo
rds and sentences for the machine to listen to and interpret will result in wrong words being interpreted b
y the system. This will make the system useless for daily communication and usage. Similarly, if we apply a
 similar noisy machine learning model (i.e. A model trend on too much noisy data for  privacy protection),
The final result when employee to real life medical applications may cause the model to miss critical featu
res in X ray or CT scan or completely false positive reports. And even worse is that missing out on feature
s in the images which point towards underlying disease may result in false negatives and the patient may be
 advised to not take any serious action. (Ahluwalia, 2021; Almsallat, 2025; Batista, 2025; Graham \u0026 Ha

In the clinical AI, It is highly Essential to hide the data And secure the data by adding noise An insured that privacy is intact as as high as possible. However, because of the trade off When too much noise is added to hide the data, the inaccuracy in the recommendations increases rapidly. Sometimes the inaccuracy goes over the roof, so much so that the recommendations become useless. Now, second problem is that if the clinical data and the recommendations of the clinical data are to be displayed on mobile system, because the mobile system are computationally weaker than any other system for example Laptop or desktop, decoding of the hidden data becomes even difficult. Devices like mobile phones prove almost useless in decoding the hidden data for the clinical AI Due to their computationally weak nature. It has to be thought about the fact that any privacy mechanism we employ, especially on mobile recommendation systems along with other platforms like your hosting server etc. has to be created dynamic in nature. Which means that if a recommendation system is being recommended on mobile phone, it is different from the one that is being recommended on a hosting website. This is because the nature of threats and attacks keep changing from time to time. Similar is the case with data distribution. For example, in the field of medical science, new diseases keep coming in. New devices are launched that may have completely different hardware and computational power, so that the privacy mechanism that worked on previous versions of the device may prove null and void in its purpose when employed in this newly launched device. This situation may put us into a situation where we are fighting with old disease with old technologies and privacy mechanism, while the new more powerful disease comes up and does damage even more rapid

ly than any disease we previously encountered with our older privacy protection mechanisms. Then again, the
 problem that comes is to find a balance between protecting the data using privacy mechanism and the accura
cy which the recommendation system as a consequence shows to the users in their device. The problem gets bi
gger and severe in more complex machine learning models like speech recognition and medical image analysis,
 where this balance between privacy and accuracy, if biased towards privacy, will result in even severely i
naccurate recommended contents. For example, in speech recognition, if we add more noise to train the syste
m with strong privacy, this extra noise when sent out to work in real environment where user will speak wo
rds and sentences for the machine to listen to and interpret will result in wrong words being interpreted b
y the system. This will make the system useless for daily communication and usage. Similarly, if we apply a
 similar noisy machine learning model (i.e. A model trend on too much noisy data for privacy protection),
The final result when employee to real life medical applications may cause the model to miss critical featu
res in X ray or CT scan or completely false positive reports. And even worse is that missing out on feature
s in the images which point towards underlying disease may result in false negatives and the patient may be
 advised to not take any serious action. (Ahluwalia, 2021; Almsallat, 2025; Batista, 2025; Graham \u0026 Ha

n.json\"} One major field where the challenge is enormous is the clinical AI. In the clinical AI, It is highly Essential to hide the data And secure the data by adding noise An insured that privacy is intact as as high as possible. However, because of the trade off When too much noise is added to hide the data, the inaccuracy in the recommendations increases rapidly. Sometimes the inaccuracy goes over the roof, so much so th

```
at the recommendations become useless. Now, second problem is that if the clinical data and the recommendat
ions of the clinical data are to be displayed on mobile system, because the mobile system are computational
ly weaker than any other system for example Laptop or desktop, decoding of the hidden data becomes even dif
ficult. Devices like mobile phones prove almost useless in decoding the hidden data for the clinical AI Due
 to their computationally weak nature. It has to be thought about the fact that any privacy mechanism we em
ploy, especially on mobile recommendation systems along with other platforms like your hosting server etc.
has to be created dynamic in nature. Which means that if a recommendation system is being recommended on mo
bile phone, it is different from the one that is being recommended on a hosting website. This is because th
e nature of threats and attacks keep changing from time to time. Similar is the case with data distribution
. For example, in the field of medical science, new diseases keep coming in. New devices are launched that
may have completely different hardware and computational power, so that the privacy mechanism that worked o
n previous versions of the device may prove null and void in its purpose when employed in this newly launch
ed device. This situation may put us into a situation where we are fighting with old disease with old techn
ologies and privacy mechanism, while the new more powerful disease comes up and does damage even more rapid
ly than any disease we previously encountered with our older privacy protection mechanisms. Then again, the
 problem that comes is to find a balance between protecting the data using privacy mechanism and the accura
cy which the recommendation system as a consequence shows to the users in their device. The problem gets bi
gger and severe in more complex machine learning models like speech recognition and medical image analysis,
 where this balance between privacy and accuracy, if biased towards privacy, will result in even severely i
naccurate recommended contents. For example, in speech recognition, if we add more noise to train the syste
m with strong  privacy, this extra noise when sent out to work in real environment where user will speak wo
rds and sentences for the machine to listen to and interpret will result in wrong words being interpreted b
y the system. This will make the system useless for daily communication and usage. Similarly, if we apply a
 similar noisy machine learning model (i.e. A model trend on too much noisy data for  privacy protection),
The final result when employee to real life medical applications may cause the model to miss critical featu
res in X ray or CT scan or completely false positive reports. And even worse is that missing out on feature
s in the images which point towards underlying disease may result in false negatives and the patient may be
 advised to not take any serious action. (Ahluwalia, 2021; Almsallat, 2025; Batista, 2025; Graham \u0026 Ha

In the clinical AI, It is highly Essential to hide the data And secure the data by adding noise An insured that privacy is intact as as high as possible. However, because of the trade off When too much noise is added to hide the data, the inaccuracy in the recommendations increases rapidly. Sometimes the inaccuracy goes over the roof, so much so that the recommendations become useless. Now, second problem is that if the clinical data and the recommendations of the clinical data are to be displayed on mobile system, because the mobile system are computationally weaker than any other system for example Laptop or desktop, decoding of the hidden data becomes even difficult. Devices like mobile phones prove almost useless in decoding the hidden data for the clinical AI Due to their computationally weak nature. It has to be thought about the fact that any privacy mechanism we employ, especially on mobile recommendation systems along with other platforms like your hosting server etc. has to be created dynamic in nature. Which means that if a recommendation system is being recommended on mobile phone, it is different from the one that is being recommended on a hosting website. This is because the nature of threats and attacks keep changing from time to time. Similar is the case with data distribution . For example, in the field of medical science, new diseases keep coming in. New devices are launched that may have completely different hardware and computational power, so that the privacy mechanism that worked on previous versions of the device may prove null and void in its purpose when employed in this newly launched device. This situation may put us into a situation where we are fighting with old disease with old technologies and privacy mechanism, while the new more powerful disease comes up and does damage even more rapidly than any disease we previously encountered with our older privacy protection mechanisms. Then again, the problem that comes is to find a balance between protecting the data using privacy mechanism and the accuracy which the recommendation system as a consequence shows to the users in their device. The problem gets bigger and severe in more complex machine learning models like speech recognition and medical image analysis, where this balance between privacy and accuracy, if biased towards privacy, will result in even severely inaccurate recommended contents. For example, in speech recognition, if we add more noise to train the system with strong privacy, this extra noise when sent out to work in real environment where user will speak words and sentences for the machine to listen to and interpret will result in wrong words being interpreted by the system. This will make the system useless for daily communication and usage. Similarly, if we apply a similar noisy machine learning model (i.e. A model trend on too much noisy data for privacy protection), The final result when employee to real life medical applications may cause the model to miss critical features in X ray or CT scan or completely false positive reports. And even worse is that missing out on features in the images which point towards underlying disease may result in false negatives and the patient may be advised to not take any serious action. In the clinical AI, It is highly Essential to hide the data And secure the data by adding noise An insured that privacy is intact as as high as possible. However, because of the trade off When too much noise is added to hide the data, the inaccuracy in the recommendations increases rapidly. Sometimes the inaccuracy goes over the roof, so much so that the recommendations become useless. Now, second problem is that if the clinical data and the recommendations of the clinical data are to be displayed on mobile system, because the mobile system are computationally weaker than any other system for example Laptop or desktop, decoding of the hidden data becomes even difficult. Devices like mobile phones prove almost useless in decoding the hidden data for the clinical AI Due to their computationally weak nature. It has to be thought about the fact that any privacy mechanism we employ, especially on mobile recommendation systems along with other platforms like your hosting server etc. has to be created dynamic in nature. Which means that if a recommendation system is being recommended on mobile phone, it is different from the one that is being recommended on a hosting website. This is because the nature of threats and attacks keep changing from time to time. Similar is the case with data distribution. For example, in the field of medical science, new diseases keep coming in. New devices are launched that may have completely different hardware and computational power, so that the privacy mechanism that worked on previous versions of the device may prove null and void in its purpose when employed in this newly launched device. This situation may put us into a situation where we are fighting with old disease with old technologies and privacy mechanism, while the new more powerful disease comes up and does damage even more rapidly than any disease we previously encountered with our older privacy protection mechanisms. Then again, the problem that comes is to find a balance between protecting the data using privacy mechanism and the accuracy which the recommendation system as a consequence shows to the users in their device. The problem gets bigger and severe in more complex machine learning models like speech recognition and medical image analysis, where this balance between privacy and accuracy, if biased towards privacy, will result in even severely inaccurate recommended contents. For example, in speech recognition, if we add more noise to train the system with strong privacy, this extra noise when sent out to work in real environment where user will speak words and sentences for the machine to listen to and interpret will result in wrong words being interpreted by the system. This will make the system useless for daily communication and usage. Similarly, if we apply a similar noisy machine learning model (i.e. A model trend on too much noisy data for privacy protection), The final result when employee to real life medical applications may cause the model to miss critical features in X ray or CT scan or completely false positive reports. And even worse is that missing out on features in the images which point towards underlying disease may result in false negatives and the patient may be

 advised to not take any serious action. (Ahluwalia, 2021; Almsallat, 2025; Batista, 2025; Graham \u0026 Ha

In the clinical AI, It is highly Essential to hide the data And secure the data by adding noise An insured that privacy is intact as as high as possible. However, because of the trade off When too much noise is added to hide the data, the inaccuracy in the recommendations increases rapidly. Sometimes the inaccuracy goes over the roof, so much so that the recommendations become useless. Now, second problem is that if the clinical data and the recommendations of the clinical data are to be displayed on mobile system, because the mobile system are computationally weaker than any other system for example Laptop or desktop, decoding of the hidden data becomes even difficult. Devices like mobile phones prove almost useless in decoding the hidden data for the clinical AI Due to their computationally weak nature. It has to be thought about the fact that any privacy mechanism we em

ploy, especially on mobile recommendation systems along with other platforms like your hosting server etc.
has to be created dynamic in nature. Which means that if a recommendation system is being recommended on mo
bile phone, it is different from the one that is being recommended on a hosting website. This is because th
e nature of threats and attacks keep changing from time to time. Similar is the case with data distribution
. For example, in the field of medical science, new diseases keep coming in. New devices are launched that
may have completely different hardware and computational power, so that the privacy mechanism that worked o
n previous versions of the device may prove null and void in its purpose when employed in this newly launch
ed device. This situation may put us into a situation where we are fighting with old disease with old techn
ologies and privacy mechanism, while the new more powerful disease comes up and does damage even more rapid
ly than any disease we previously encountered with our older privacy protection mechanisms. Then again, the
 problem that comes is to find a balance between protecting the data using privacy mechanism and the accura
cy which the recommendation system as a consequence shows to the users in their device. The problem gets bi
gger and severe in more complex machine learning models like speech recognition and medical image analysis,
 where this balance between privacy and accuracy, if biased towards privacy, will result in even severely i
naccurate recommended contents. For example, in speech recognition, if we add more noise to train the syste
m with strong privacy, this extra noise when sent out to work in real environment where user will speak wo
rds and sentences for the machine to listen to and interpret will result in wrong words being interpreted b
y the system. This will make the system useless for daily communication and usage. Similarly, if we apply a
 similar noisy machine learning model (i.e. A model trend on too much noisy data for privacy protection),
The final result when employee to real life medical applications may cause the model to miss critical featu
res in X ray or CT scan or completely false positive reports. And even worse is that missing out on feature
s in the images which point towards underlying disease may result in false negatives and the patient may be
 advised to not take any serious action. (Ahluwalia, 2021; Almsallat, 2025; Batista, 2025; Graham \u0026 Ha

n.json\"} One major field where the challenge is enormous is the clinical AI. In the clinical AI, It is hig
hly Essential to hide the data And secure the data by adding noise An insured that privacy is intact as as
high as possible. However, because of the trade off When too much noise is added to hide the data, the inac
curacy in the recommendations increases rapidly. Sometimes the inaccuracy goes over the roof, so much so th
at the recommendations become useless. Now, second problem is that if the clinical data and the recommendat
ions of the clinical data are to be displayed on mobile system, because the mobile system are computational
ly weaker than any other system for example Laptop or desktop, decoding of the hidden data becomes even dif
ficult. Devices like mobile phones prove almost useless in decoding the hidden data for the clinical AI Due
 to their computationally weak nature. It has to be thought about the fact that any privacy mechanism we em
ploy, especially on mobile recommendation systems along with other platforms like your hosting server etc.
has to be created dynamic in nature. Which means that if a recommendation system is being recommended on mo
bile phone, it is different from the one that is being recommended on a hosting website. This is because th
e nature of threats and attacks keep changing from time to time. Similar is the case with data distribution
. For example, in the field of medical science, new diseases keep coming in. New devices are launched that
may have completely different hardware and computational power, so that the privacy mechanism that worked o
n previous versions of the device may prove null and void in its purpose when employed in this newly launch
ed device. This situation may put us into a situation where we are fighting with old disease with old techn
ologies and privacy mechanism, while the new more powerful disease comes up and does damage even more rapid
ly than any disease we previously encountered with our older privacy protection mechanisms. Then again, the
 problem that comes is to find a balance between protecting the data using privacy mechanism and the accura
cy which the recommendation system as a consequence shows to the users in their device. The problem gets bi
gger and severe in more complex machine learning models like speech recognition and medical image analysis,
 where this balance between privacy and accuracy, if biased towards privacy, will result in even severely i
naccurate recommended contents. For example, in speech recognition, if we add more noise to train the syste
m with strong  privacy, this extra noise when sent out to work in real environment where user will speak wo
rds and sentences for the machine to listen to and interpret will result in wrong words being interpreted b
y the system. This will make the system useless for daily communication and usage. Similarly, if we apply a
 similar noisy machine learning model (i.e. A model trend on too much noisy data for  privacy protection),
The final result when employee to real life medical applications may cause the model to miss critical featu
res in X ray or CT scan or completely false positive reports. And even worse is that missing out on feature
s in the images which point towards underlying disease may result in false negatives and the patient may be
 advised to not take any serious action. (Ahluwalia, 2021; Almsallat, 2025; Batista, 2025; Graham \u0026 Ha

In the clinical AI, It is highly Essential to hide the data And secure the data by adding noise An insured that privacy is intact as as high as possible. However, because of the trade off When too much noise is added to hide the data, the inaccuracy in the recommendations increases rapidly. Sometimes the inaccuracy goes over the roof, so much so that the recommendations become useless. Now, second problem is that if the clinical data and the recommendations of the clinical data are to be displayed on mobile system, because the mobile system are computationally weaker than any other system for example Laptop or desktop, decoding of the hidden data becomes even difficult. Devices like mobile phones prove almost useless in decoding the hidden data for the clinical AI Due to their computationally weak nature. It has to be thought about the fact that any privacy mechanism we employ, especially on mobile recommendation systems along with other platforms like your hosting server etc. has to be created dynamic in nature. Which means that if a recommendation system is being recommended on mobile phone, it is different from the one that is being recommended on a hosting website. This is because the nature of threats and attacks keep changing from time to time. Similar is the case with data distribution. For example, in the field of medical science, new diseases keep coming in. New devices are launched that may have completely different hardware and computational power, so that the privacy mechanism that worked on previous versions of the device may prove null and void in its purpose when employed in this newly launched device. This situation may put us into a situation where we are fighting with old disease with old technologies and privacy mechanism, while the new more powerful disease comes up and does damage even more rapidly than any disease we previously encountered with our older privacy protection mechanisms. Then again, the problem that comes is to find a balance between protecting the data using privacy mechanism and the accuracy which the recommendation system as a consequence shows to the users in their device. The problem gets bigger and severe in more complex machine learning models like speech recognition and medical image analysis, where this balance between privacy and accuracy, if biased towards privacy, will result in even severely inaccurate recommended contents. For example, in speech recognition, if we add more noise to train the system with strong privacy, this extra noise when sent out to work in real environment where user will speak words and sentences for the machine to listen to and interpret will result in wrong words being interpreted by the system. This will make the system useless for daily communication and usage. Similarly, if we apply a similar noisy machine learning model (i.e. A model trend on too much noisy data for privacy protection), The final result when employee to real life medical applications may cause the model to miss critical features in X ray or CT scan or completely false positive reports. And even worse is that missing out on features in the images which point towards underlying disease may result in false negatives and the patient may be advised to not take any serious action. In the clinical AI, It is highly Essential to hide the data And secure the data by adding noise An insured that privacy is intact as as high as possible. However, because of the trade off When too much noise is added to hide the data, the inaccuracy in the recommendations increases rapidly. Sometimes the inaccuracy goes over the roof, so much so that the recommendations become useless. Now, second problem is that if the clinical data and the recommendations of the clinical data are to be displayed on mobile system, because the mobile system are computationally weaker than any other system for example Laptop or desktop, decoding of the hidden data becomes even difficult. Devices like mobile phones prove almost useless in decoding the hidden data for the clinical AI Due to their computationally weak nature. It has to be thought about the fact that any privacy mechanism we employ, especially on mobile recommendation systems along with other platforms like your hosting server etc. has to be created dynamic in nature. Which means that if a recommendation system is being recommended on mobile phone, it is different from the one that is being recommended on a hosting website. This is because the nature of threats and attacks keep changing from time to time. Similar is the case with data distribution. For example, in the field of medical science, new diseases keep coming in. New devices are launched that may have completely different hardware and computational power, so that the privacy mechanism that worked on previous versions of the device may prove null and void in its purpose when employed in this newly launched device. This situation may put us into a situation where we are fighting with old disease with old technologies and privacy mechanism, while the new more powerful disease comes up and does damage even more rapidly than any disease we previously encountered with our older privacy protection mechanisms. Then again, the problem that comes is to find a balance between protecting the data using privacy mechanism and the accuracy which the recommendation system as a consequence shows to the users in their device. The problem gets bi

```
gger and severe in more complex machine learning models like speech recognition and medical image analysis,
 where this balance between privacy and accuracy, if biased towards privacy, will result in even severely i
naccurate recommended contents. For example, in speech recognition, if we add more noise to train the syste
m with strong  privacy, this extra noise when sent out to work in real environment where user will speak wo
rds and sentences for the machine to listen to and interpret will result in wrong words being interpreted b
y the system. This will make the system useless for daily communication and usage. Similarly, if we apply a
 similar noisy machine learning model (i.e. A model trend on too much noisy data for  privacy protection),
The final result when employee to real life medical applications may cause the model to miss critical featu
res in X ray or CT scan or completely false positive reports. And even worse is that missing out on feature
s in the images which point towards underlying disease may result in false negatives and the patient may be
 advised to not take any serious action. (Ahluwalia, 2021; Almsallat, 2025; Batista, 2025; Graham \u0026 Ha

ts\":[[\"2025\"]]}}}],\"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citatio
n.json\"} One major field where the challenge is enormous is the clinical AI. In the clinical AI, It is hig
hly Essential to hide the data And secure the data by adding noise An insured that privacy is intact as as
high as possible. However, because of the trade off When too much noise is added to hide the data, the inac
curacy in the recommendations increases rapidly. Sometimes the inaccuracy goes over the roof, so much so th
at the recommendations become useless. Now, second problem is that if the clinical data and the recommendat
ions of the clinical data are to be displayed on mobile system, because the mobile system are computational
ly weaker than any other system for example Laptop or desktop, decoding of the hidden data becomes even dif
ficult. Devices like mobile phones prove almost useless in decoding the hidden data for the clinical AI Due
 to their computationally weak nature. It has to be thought about the fact that any privacy mechanism we em
ploy, especially on mobile recommendation systems along with other platforms like your hosting server etc.
has to be created dynamic in nature. Which means that if a recommendation system is being recommended on mo
bile phone, it is different from the one that is being recommended on a hosting website. This is because th
e nature of threats and attacks keep changing from time to time. Similar is the case with data distribution
. For example, in the field of medical science, new diseases keep coming in. New devices are launched that
may have completely different hardware and computational power, so that the privacy mechanism that worked o
n previous versions of the device may prove null and void in its purpose when employed in this newly launch
ed device. This situation may put us into a situation where we are fighting with old disease with old techn
ologies and privacy mechanism, while the new more powerful disease comes up and does damage even more rapid
ly than any disease we previously encountered with our older privacy protection mechanisms. Then again, the
 problem that comes is to find a balance between protecting the data using privacy mechanism and the accura
cy which the recommendation system as a consequence shows to the users in their device. The problem gets bi
gger and severe in more complex machine learning models like speech recognition and medical image analysis,
 where this balance between privacy and accuracy, if biased towards privacy, will result in even severely i
naccurate recommended contents. For example, in speech recognition, if we add more noise to train the syste
m with strong privacy, this extra noise when sent out to work in real environment where user will speak wo
rds and sentences for the machine to listen to and interpret will result in wrong words being interpreted b
y the system. This will make the system useless for daily communication and usage. Similarly, if we apply a
 similar noisy machine learning model (i.e. A model trend on too much noisy data for privacy protection),
The final result when employee to real life medical applications may cause the model to miss critical featu
res in X ray or CT scan or completely false positive reports. And even worse is that missing out on feature
s in the images which point towards underlying disease may result in false negatives and the patient may be
 advised to not take any serious action. (Ahluwalia, 2021; Almsallat, 2025; Batista, 2025; Graham \u0026 Ha

ts\":[[\"2025\"]]}}}],\"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citatio
n.json\"} One major field where the challenge is enormous is the clinical AI. In the clinical AI, It is hig
hly Essential to hide the data And secure the data by adding noise An insured that privacy is intact as as
high as possible. However, because of the trade off When too much noise is added to hide the data, the inac
curacy in the recommendations increases rapidly. Sometimes the inaccuracy goes over the roof, so much so th
at the recommendations become useless. Now, second problem is that if the clinical data and the recommendat
ions of the clinical data are to be displayed on mobile system, because the mobile system are computational
ly weaker than any other system for example Laptop or desktop, decoding of the hidden data becomes even dif
ficult. Devices like mobile phones prove almost useless in decoding the hidden data for the clinical AI Due
 to their computationally weak nature. It has to be thought about the fact that any privacy mechanism we em
ploy, especially on mobile recommendation systems along with other platforms like your hosting server etc.
has to be created dynamic in nature. Which means that if a recommendation system is being recommended on mo
bile phone, it is different from the one that is being recommended on a hosting website. This is because th
e nature of threats and attacks keep changing from time to time. Similar is the case with data distribution
. For example, in the field of medical science, new diseases keep coming in. New devices are launched that
may have completely different hardware and computational power, so that the privacy mechanism that worked o
n previous versions of the device may prove null and void in its purpose when employed in this newly launch
ed device. This situation may put us into a situation where we are fighting with old disease with old techn
ologies and privacy mechanism, while the new more powerful disease comes up and does damage even more rapid
ly than any disease we previously encountered with our older privacy protection mechanisms. Then again, the
 problem that comes is to find a balance between protecting the data using privacy mechanism and the accura
cy which the recommendation system as a consequence shows to the users in their device. The problem gets bi
gger and severe in more complex machine learning models like speech recognition and medical image analysis,
 where this balance between privacy and accuracy, if biased towards privacy, will result in even severely i
naccurate recommended contents. For example, in speech recognition, if we add more noise to train the syste
m with strong  privacy, this extra noise when sent out to work in real environment where user will speak wo
rds and sentences for the machine to listen to and interpret will result in wrong words being interpreted b
y the system. This will make the system useless for daily communication and usage. Similarly, if we apply a
 similar noisy machine learning model (i.e. A model trend on too much noisy data for  privacy protection),
The final result when employee to real life medical applications may cause the model to miss critical featu
res in X ray or CT scan or completely false positive reports. And even worse is that missing out on feature
s in the images which point towards underlying disease may result in false negatives and the patient may be
 advised to not take any serious action. (Ahluwalia, 2021; Almsallat, 2025; Batista, 2025; Graham \u0026 Ha

In the clinical AI, It is highly Essential to hide the data And secure the data by adding noise An insured that privacy is intact as as high as possible. However, because of the trade off When too much noise is added to hide the data, the inaccuracy in the recommendations increases rapidly. Sometimes the inaccuracy goes over the roof, so much so that the recommendations become useless. Now, second problem is that if the clinical data and the recommendations of the clinical data are to be displayed on mobile system, because the mobile system are computationally weaker than any other system for example Laptop or desktop, decoding of the hidden data becomes even difficult. Devices like mobile phones prove almost useless in decoding the hidden data for the clinical AI Due to their computationally weak nature. It has to be thought about the fact that any privacy mechanism we employ, especially on mobile recommendation systems along with other platforms like your hosting server etc. has to be created dynamic in nature. Which means that if a recommendation system is being recommended on mobile phone, it is different from the one that is being recommended on a hosting website. This is because the nature of threats and attacks keep changing from time to time. Similar is the case with data distribution. For example, in the field of medical science, new diseases keep coming in. New devices are launched that may have completely different hardware and computational power, so that the privacy mechanism that worked on previous versions of the device may prove null and void in its purpose when employed in this newly launched device. This situation may put us into a situation where we are fighting with old disease with old technologies and privacy mechanism, while the new more powerful disease comes up and does damage even more rapidly than any disease we previously encountered with our older privacy protection mechanisms. Then again, the problem that comes is to find a balance between protecting the data using privacy mechanism and the accuracy which the recommendation system as a consequence shows to the users in their device. The problem gets bigger and severe in more complex machine learning models like speech recognition and medical image analysis, where this balance between privacy and accuracy, if biased towards privacy, will result in even severely inaccurate recommended contents. For example, in speech recognition, if we add more noise to train the system with strong privacy, this extra noise when sent out to work in real environment where user will speak words and sentences for the machine to listen to and interpret will result in wrong words being interpreted by the system. This will make the system useless for daily communication and usage. Similarly, if we apply a similar noisy machine learning model (i.e. A model trend on too much noisy data for privacy protection), The final result when employee to real life medical applications may cause the model to miss critical features in X ray or CT scan or completely false positive reports. And even worse is that missing out on features in the images which point towards underlying disease may result in false negatives and the patient may be

ts\":[[\"2025\"]]}}}],\"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citatio
n.json\"} One major field where the challenge is enormous is the clinical AI. In the clinical AI, It is hig

```
hly Essential to hide the data And secure the data by adding noise An insured that privacy is intact as as
high as possible. However, because of the trade off When too much noise is added to hide the data, the inac
curacy in the recommendations increases rapidly. Sometimes the inaccuracy goes over the roof, so much so th
at the recommendations become useless. Now, second problem is that if the clinical data and the recommendat
ions of the clinical data are to be displayed on mobile system, because the mobile system are computational
ly weaker than any other system for example Laptop or desktop, decoding of the hidden data becomes even dif
ficult. Devices like mobile phones prove almost useless in decoding the hidden data for the clinical AI Due
 to their computationally weak nature. It has to be thought about the fact that any privacy mechanism we em
ploy, especially on mobile recommendation systems along with other platforms like your hosting server etc.
has to be created dynamic in nature. Which means that if a recommendation system is being recommended on mo
bile phone, it is different from the one that is being recommended on a hosting website. This is because th
e nature of threats and attacks keep changing from time to time. Similar is the case with data distribution
. For example, in the field of medical science, new diseases keep coming in. New devices are launched that
may have completely different hardware and computational power, so that the privacy mechanism that worked o
n previous versions of the device may prove null and void in its purpose when employed in this newly launch
ed device. This situation may put us into a situation where we are fighting with old disease with old techn
ologies and privacy mechanism, while the new more powerful disease comes up and does damage even more rapid
ly than any disease we previously encountered with our older privacy protection mechanisms. Then again, the
 problem that comes is to find a balance between protecting the data using privacy mechanism and the accura
cy which the recommendation system as a consequence shows to the users in their device. The problem gets bi
gger and severe in more complex machine learning models like speech recognition and medical image analysis,
 where this balance between privacy and accuracy, if biased towards privacy, will result in even severely i
naccurate recommended contents. For example, in speech recognition, if we add more noise to train the syste
m with strong  privacy, this extra noise when sent out to work in real environment where user will speak wo
rds and sentences for the machine to listen to and interpret will result in wrong words being interpreted b
y the system. This will make the system useless for daily communication and usage. Similarly, if we apply a
 similar noisy machine learning model (i.e. A model trend on too much noisy data for  privacy protection),
The final result when employee to real life medical applications may cause the model to miss critical featu
res in X ray or CT scan or completely false positive reports. And even worse is that missing out on feature
s in the images which point towards underlying disease may result in false negatives and the patient may be
 advised to not take any serious action. (Ahluwalia, 2021; Almsallat, 2025; Batista, 2025; Graham \u0026 Ha

n.json\"} One major field where the challenge is enormous is the clinical AI. In the clinical AI, It is highly Essential to hide the data And secure the data by adding noise An insured that privacy is intact as as high as possible. However, because of the trade off When too much noise is added to hide the data, the inaccuracy in the recommendations increases rapidly. Sometimes the inaccuracy goes over the roof, so much so that the recommendations become useless. Now, second problem is that if the clinical data and the recommendations of the clinical data are to be displayed on mobile system, because the mobile system are computationally weaker than any other system for example Laptop or desktop, decoding of the hidden data becomes even difficult. Devices like mobile phones prove almost useless in decoding the hidden data for the clinical AI Due to their computationally weak nature. It has to be thought about the fact that any privacy mechanism we employ, especially on mobile recommendation systems along with other platforms like your hosting server etc. has to be created dynamic in nature. Which means that if a recommendation system is being recommended on mobile phone, it is different from the one that is being recommended on a hosting website. This is because the nature of threats and attacks keep changing from time to time. Similar is the case with data distribution. For example, in the field of medical science, new diseases keep coming in. New devices are launched that may have completely different hardware and computational power, so that the privacy mechanism that worked on previous versions of the device may prove null and void in its purpose when employed in this newly launched device. This situation may put us into a situation where we are fighting with old disease with old technologies and privacy mechanism, while the new more powerful disease comes up and does damage even more rapidly than any disease we previously encountered with our older privacy protection mechanisms. Then again, the problem that comes is to find a balance between protecting the data using privacy mechanism and the accuracy which the recommendation system as a consequence shows to the users in their device. The problem gets bigger and severe in more complex machine learning models like speech recognition and medical image analysis, where this balance between privacy and accuracy, if biased towards privacy, will result in even severely inaccurate recommended contents. For example, in speech recognition, if we add more noise to train the system with strong privacy, this extra noise when sent out to work in real environment where user will speak words and sentences for the machine to listen to and interpret will result in wrong words being interpreted by the system. This will make the system useless for daily communication and usage. Similarly, if we apply a similar noisy machine learning model (i.e. A model trend on too much noisy data for privacy protection), The final result when employee to real life medical applications may cause the model to miss critical features in X ray or CT scan or completely false positive reports. And even worse is that missing out on features in the images which point towards underlying disease may result in false negatives and the patient may be advised to not take any serious action. This means that if privacy mechanisms are not designed with proper balance and buyers and equity, the model may end up discriminating between different user groups or users data. In other words, the noise which is added to the data may be proportional to the magnitude of the data point. So if this kind of noise is propagated into the model the data set may start collecting into groups of small sub data (as in unsupervised learning) and the whole data set may end up looking like a collection of lumps of data at many different places on the graph. Here lies another problem. User who contribute rare type of data, for example some users may like very rare genre of movies. If we apply equitable noise to the data set of all the users these rare contributions may for sure will get clocked in too much of noise and the system may not learn much about these rare data set types and hence perform poorly. Because the whole point of Federated learning is to hide the raw data of the user, it is therefore almost impossible to tell whether the system is recommending content in all fairness to all users or not. Privacy and fairness cannot go hand in hand at some instances. The simple fact that if privacy mechanisms and measures are not designed with fairness in mind, they can lead to harming minority group of users. Especially though group of users who contribute rare genre of data set. To resolve this dilemma, we can deploy what is called “personalised privacy”. In this what happens is that the privacy protection is tailored to each user according to the data the user generates. This helps in keeping sensitive information of each user safe while at the same time system works efficiently and reliably from for each user. A new strategy is proposed known as “multi objective optimization” to handle fairness and privacy tag of work and create a balance between all the groups so that no group of users is left behind with useless recommendations on their devices. This strategy has a goal to find an optimal point among accuracy, privacy and fairness, all at the same time. There are also some technical challenges like a privacy technique named Poisson subsampling which can put too much load on the low end mobile phones or hardware and their CPU. This will exclude users who possess older phones and hence will collect correct data from only users that have high end specifications mobile phones and devices especially when they are new. Consequently the unfairness. This leads us to a warning named Matthew effect warning. It says that privacy if focused on while creating a privacy system without bringing into the game fairness, then the resulting model of Federated learning will reinforce or amplify already existing inequalities making the “poor even poorer”. This means that if privacy mechanisms are not designed with proper balance and buyers and equity, the model may end up discriminating between different user groups or users data. In other words, the noise which is added to the data may be proportional to the magnitude of the data point. So if this kind of noise is propagated into the model the data set may start collecting into groups of small sub data (as in unsupervised learning) and the whole data set may end up looking like a collection of lumps of data at many different places on the graph. Here lies another problem. User who contribute rare type of data, for example some users may like very rare genre of movies. If we apply equitable noise to the data set of all the users these rare contributions may for sure will get clocked in too much of noise and the system may not learn much about these rare data set types and hence perform poorly. Because the whole point of Federated learning is to hide the raw data of the user, it is therefore almost impossible to tell whether the system is recommending content in all fairness to all users or not. Privacy and fairness cannot go hand in hand at some instances. The simple fact

```
 that if privacy mechanisms and measures are not designed with fairness in mind, they can lead to harming m
inority group of users. Especially though group of users who contribute rare genre of data set. To resolve 
this dilemma, we can deploy what is called “personalised privacy”. In this what happens is that the privacy
 protection is tailored to each user according to the data the user generates. This helps in keeping sensit
ive information of each user safe while at the same time system works efficiently and reliably from for eac
h user. A new strategy is proposed known as “multi objective optimization” to handle fairness and privacy t
ag of work and create a balance between all the groups so that no group of users is left behind with useles
s recommendations on their devices. This strategy has a goal to find an optimal point among accuracy, priva
cy and fairness, all at the same time. There are also some technical challenges like a privacy technique na
med Poisson subsampling which can put too much load on the low end mobile phones or hardware and their CPU.
 This will exclude users who possess older phones and hence will collect correct data from only users that 
have high end specifications mobile phones and devices especially when they are new. Consequently the unfai
rness. This leads us to a warning named Matthew effect warning. It says that privacy if focused on while cr
eating a privacy system without bringing into the game fairness, then the resulting model of Federated lear
ning will reinforce or amplify already existing inequalities making the “poor even poorer”. (Badar et al.,

\"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} Apart from the noise accuracy trade-off in privacy, there is one more problem known as “poor gets poorer”. This means that if privacy mechanisms are not designed with proper balance and buyers and equity, the model may end up discriminating between different user groups or users data. In other words, the noise which is added to the data may be proportional to the magnitude of the data point. So if this kind of noise is propagated into the model the data set may start collecting into groups of small sub data (as in unsupervised learning) and the whole data set may end up looking like a collection of lumps of data at many different places on the graph. Here lies another problem. User who contribute rare type of data, for example some users may like very rare genre of movies. If we apply equitable noise to the data set of all the users these rare contributions may for sure will get clocked in too much of noise and the system may not learn much about these rare data set types and hence perform poorly. Because the whole point of Federated learning is to hide the raw data of the user, it is therefore almost impossible to tell whether the system is recommending content in all fairness to all users or not. Privacy and fairness cannot go hand in hand at some instances. The simple fact that if privacy mechanisms and measures are not designed with fairness in mind, they can lead to harming minority group of users. Especially though group of users who contribute rare genre of data set. To resolve this dilemma, we can deploy what is called “personalised privacy”. In this what happens is that the privacy

protection is tailored to each user according to the data the user generates. This helps in keeping sensitive information of each user safe while at the same time system works efficiently and reliably from for each user. A new strategy is proposed known as “multi objective optimization” to handle fairness and privacy tag of work and create a balance between all the groups so that no group of users is left behind with useless recommendations on their devices. This strategy has a goal to find an optimal point among accuracy, privacy and fairness, all at the same time. There are also some technical challenges like a privacy technique named Poisson subsampling which can put too much load on the low end mobile phones or hardware and their CPU. This will exclude users who possess older phones and hence will collect correct data from only users that have high end specifications mobile phones and devices especially when they are new. Consequently the unfairness. This leads us to a warning named Matthew effect warning. It says that privacy if focused on while creating a privacy system without bringing into the game fairness, then the resulting model of Federated learning will reinforce or amplify already existing inequalities making the “poor even poorer”. \"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} Apart from t
he noise accuracy trade-off in privacy, there is one more problem known as “poor gets poorer”. This means t
hat if privacy mechanisms are not designed with proper balance and buyers and equity, the model may end up
discriminating between different user groups or users data. In other words, the noise which is added to the
 data may be proportional to the magnitude of the data point. So if this kind of noise is propagated into t
he model the data set may start collecting into groups of small sub data (as in unsupervised learning) and
the whole data set may end up looking like a collection of lumps of data at many different places on the gr
aph. Here lies another problem. User who contribute rare type of data, for example some users may like very
 rare genre of movies. If we apply equitable noise to the data set of all the users these rare contribution
s may for sure will get clocked in too much of noise and the system may not learn much about these rare dat
a set types and hence perform poorly. Because the whole point of Federated learning is to hide the raw data
 of the user, it is therefore almost impossible to tell whether the system is recommending content in all f
airness to all users or not. Privacy and fairness cannot go hand in hand at some instances. The simple fact
 that if privacy mechanisms and measures are not designed with fairness in mind, they can lead to harming m
inority group of users. Especially though group of users who contribute rare genre of data set. To resolve
this dilemma, we can deploy what is called “personalised privacy”. In this what happens is that the privacy
 protection is tailored to each user according to the data the user generates. This helps in keeping sensit
ive information of each user safe while at the same time system works efficiently and reliably from for eac
h user. A new strategy is proposed known as “multi objective optimization” to handle fairness and privacy t
ag of work and create a balance between all the groups so that no group of users is left behind with useles
s recommendations on their devices. This strategy has a goal to find an optimal point among accuracy, priva
cy and fairness, all at the same time. There are also some technical challenges like a privacy technique na
med Poisson subsampling which can put too much load on the low end mobile phones or hardware and their CPU.
 This will exclude users who possess older phones and hence will collect correct data from only users that
have high end specifications mobile phones and devices especially when they are new. Consequently the unfai
rness. This leads us to a warning named Matthew effect warning. It says that privacy if focused on while cr
eating a privacy system without bringing into the game fairness, then the resulting model of Federated lear
ning will reinforce or amplify already existing inequalities making the “poor even poorer”. (Badar et al.,

\"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} Apart from t
he noise accuracy trade-off in privacy, there is one more problem known as “poor gets poorer”. This means t
hat if privacy mechanisms are not designed with proper balance and buyers and equity, the model may end up
discriminating between different user groups or users data. In other words, the noise which is added to the
 data may be proportional to the magnitude of the data point. So if this kind of noise is propagated into t
he model the data set may start collecting into groups of small sub data (as in unsupervised learning) and
the whole data set may end up looking like a collection of lumps of data at many different places on the gr
aph. Here lies another problem. User who contribute rare type of data, for example some users may like very
 rare genre of movies. If we apply equitable noise to the data set of all the users these rare contribution
s may for sure will get clocked in too much of noise and the system may not learn much about these rare dat
a set types and hence perform poorly. Because the whole point of Federated learning is to hide the raw data
 of the user, it is therefore almost impossible to tell whether the system is recommending content in all f
airness to all users or not. Privacy and fairness cannot go hand in hand at some instances. The simple fact
 that if privacy mechanisms and measures are not designed with fairness in mind, they can lead to harming m
inority group of users. Especially though group of users who contribute rare genre of data set. To resolve
this dilemma, we can deploy what is called “personalised privacy”. In this what happens is that the privacy
 protection is tailored to each user according to the data the user generates. This helps in keeping sensit
ive information of each user safe while at the same time system works efficiently and reliably from for eac
h user. A new strategy is proposed known as “multi objective optimization” to handle fairness and privacy t
ag of work and create a balance between all the groups so that no group of users is left behind with useles
s recommendations on their devices. This strategy has a goal to find an optimal point among accuracy, priva
cy and fairness, all at the same time. There are also some technical challenges like a privacy technique na
med Poisson subsampling which can put too much load on the low end mobile phones or hardware and their CPU.
 This will exclude users who possess older phones and hence will collect correct data from only users that
have high end specifications mobile phones and devices especially when they are new. Consequently the unfai
rness. This leads us to a warning named Matthew effect warning. It says that privacy if focused on while cr
eating a privacy system without bringing into the game fairness, then the resulting model of Federated lear
ning will reinforce or amplify already existing inequalities making the “poor even poorer”. (Badar et al.,

\"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} Apart from the noise accuracy trade-off in privacy, there is one more problem known as “poor gets poorer”. This means that if privacy mechanisms are not designed with proper balance and buyers and equity, the model may end up discriminating between different user groups or users data. In other words, the noise which is added to the data may be proportional to the magnitude of the data point. So if this kind of noise is propagated into the model the data set may start collecting into groups of small sub data (as in unsupervised learning) and the whole data set may end up looking like a collection of lumps of data at many different places on the graph. Here lies another problem. User who contribute rare type of data, for example some users may like very rare genre of movies. If we apply equitable noise to the data set of all the users these rare contributions may for sure will get clocked in too much of noise and the system may not learn much about these rare data set types and hence perform poorly. Because the whole point of Federated learning is to hide the raw data of the user, it is therefore almost impossible to tell whether the system is recommending content in all fairness to all users or not. Privacy and fairness cannot go hand in hand at some instances. The simple fact that if privacy mechanisms and measures are not designed with fairness in mind, they can lead to harming minority group of users. Especially though group of users who contribute rare genre of data set. To resolve this dilemma, we can deploy what is called “personalised privacy”. In this what happens is that the privacy protection is tailored to each user according to the data the user generates. This helps in keeping sensitive information of each user safe while at the same time system works efficiently and reliably from for each user. A new strategy is proposed known as “multi objective optimization” to handle fairness and privacy tag of work and create a balance between all the groups so that no group of users is left behind with useless recommendations on their devices. This strategy has a goal to find an optimal point among accuracy, privacy and fairness, all at the same time. There are also some technical challenges like a privacy technique named Poisson subsampling which can put too much load on the low end mobile phones or hardware and their CPU. This will exclude users who possess older phones and hence will collect correct data from only users that have high end specifications mobile phones and devices especially when they are new. Consequently the unfairness. This leads us to a warning named Matthew effect warning. It says that privacy if focused on while creating a privacy system without bringing into the game fairness, then the resulting model of Federated learning will reinforce or amplify already existing inequalities making the “poor even poorer”. \"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} Apart from t
he noise accuracy trade-off in privacy, there is one more problem known as “poor gets poorer”. This means t
hat if privacy mechanisms are not designed with proper balance and buyers and equity, the model may end up
discriminating between different user groups or users data. In other words, the noise which is added to the
 data may be proportional to the magnitude of the data point. So if this kind of noise is propagated into t
he model the data set may start collecting into groups of small sub data (as in unsupervised learning) and
the whole data set may end up looking like a collection of lumps of data at many different places on the gr
aph. Here lies another problem. User who contribute rare type of data, for example some users may like very
 rare genre of movies. If we apply equitable noise to the data set of all the users these rare contribution
s may for sure will get clocked in too much of noise and the system may not learn much about these rare dat
a set types and hence perform poorly. Because the whole point of Federated learning is to hide the raw data
 of the user, it is therefore almost impossible to tell whether the system is recommending content in all f
airness to all users or not. Privacy and fairness cannot go hand in hand at some instances. The simple fact
 that if privacy mechanisms and measures are not designed with fairness in mind, they can lead to harming m
inority group of users. Especially though group of users who contribute rare genre of data set. To resolve
this dilemma, we can deploy what is called “personalised privacy”. In this what happens is that the privacy
 protection is tailored to each user according to the data the user generates. This helps in keeping sensit
ive information of each user safe while at the same time system works efficiently and reliably from for eac
h user. A new strategy is proposed known as “multi objective optimization” to handle fairness and privacy t
ag of work and create a balance between all the groups so that no group of users is left behind with useles
s recommendations on their devices. This strategy has a goal to find an optimal point among accuracy, priva
cy and fairness, all at the same time. There are also some technical challenges like a privacy technique na
med Poisson subsampling which can put too much load on the low end mobile phones or hardware and their CPU.
 This will exclude users who possess older phones and hence will collect correct data from only users that
have high end specifications mobile phones and devices especially when they are new. Consequently the unfai
rness. This leads us to a warning named Matthew effect warning. It says that privacy if focused on while cr
eating a privacy system without bringing into the game fairness, then the resulting model of Federated lear
ning will reinforce or amplify already existing inequalities making the “poor even poorer”. (Badar et al.,

\"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} Apart from the noise accuracy trade-off in privacy, there is one more problem known as “poor gets poorer”. This means that if privacy mechanisms are not designed with proper balance and buyers and equity, the model may end up discriminating between different user groups or users data. In other words, the noise which is added to the data may be proportional to the magnitude of the data point. So if this kind of noise is propagated into the model the data set may start collecting into groups of small sub data (as in unsupervised learning) and the whole data set may end up looking like a collection of lumps of data at many different places on the graph. Here lies another problem. User who contribute rare type of data, for example some users may like very rare genre of movies. If we apply equitable noise to the data set of all the users these rare contributions may for sure will get clocked in too much of noise and the system may not learn much about these rare data set types and hence perform poorly. Because the whole point of Federated learning is to hide the raw data of the user, it is therefore almost impossible to tell whether the system is recommending content in all fairness to all users or not. Privacy and fairness cannot go hand in hand at some instances. The simple fact that if privacy mechanisms and measures are not designed with fairness in mind, they can lead to harming minority group of users. Especially though group of users who contribute rare genre of data set. To resolve this dilemma, we can deploy what is called “personalised privacy”. In this what happens is that the privacy protection is tailored to each user according to the data the user generates. This helps in keeping sensitive information of each user safe while at the same time system works efficiently and reliably from for each user. A new strategy is proposed known as “multi objective optimization” to handle fairness and privacy tag of work and create a balance between all the groups so that no group of users is left behind with useless recommendations on their devices. This strategy has a goal to find an optimal point among accuracy, privacy and fairness, all at the same time. There are also some technical challenges like a privacy technique named Poisson subsampling which can put too much load on the low end mobile phones or hardware and their CPU. This will exclude users who possess older phones and hence will collect correct data from only users that have high end specifications mobile phones and devices especially when they are new. Consequently the unfairness. This leads us to a warning named Matthew effect warning. It says that privacy if focused on while creating a privacy system without bringing into the game fairness, then the resulting model of Federated lear

This means that if privacy mechanisms are not designed with proper balance and buyers and equity, the model may end up discriminating between different user groups or users data. In other words, the noise which is added to the data may be proportional to the magnitude of the data point. So if this kind of noise is propagated into the model the data set may start collecting into groups of small sub data (as in unsupervised learning) and the whole data set may end up looking like a collection of lumps of data at many different places on the graph. Here lies another problem. User who contribute rare type of data, for example some users may like very rare genre of movies. If we apply equitable noise to the data set of all the users these rare contributions may for sure will get clocked in too much of noise and the system may not learn much about these rare data set types and hence perform poorly. Because the whole point of Federated learning is to hide the raw data of the user, it is therefore almost impossible to tell whether the system is recommending content in all fairness to all users or not. Privacy and fairness cannot go hand in hand at some instances. The simple fact that if privacy mechanisms and measures are not designed with fairness in mind, they can lead to harming minority group of users. Especially though group of users who contribute rare genre of data set. To resolve this dilemma, we can deploy what is called “personalised privacy”. In this what happens is that the privacy protection is tailored to each user according to the data the user generates. This helps in keeping sensitive information of each user safe while at the same time system works efficiently and reliably from for each user. A new strategy is proposed known as “multi objective optimization” to handle fairness and privacy tag of work and create a balance between all the groups so that no group of users is left behind with useless recommendations on their devices. This strategy has a goal to find an optimal point among accuracy, privacy and fairness, all at the same time. There are also some technical challenges like a privacy technique named Poisson subsampling which can put too much load on the low end mobile phones or hardware and their CPU. This will exclude users who possess older phones and hence will collect correct data from only users that have high end specifications mobile phones and devices especially when they are new. Consequently the unfairness. This leads us to a warning named Matthew effect warning. It says that privacy if focused on while creating a privacy system without bringing into the game fairness, then the resulting model of Federated learning will reinforce or amplify already existing inequalities making the “poor even poorer”. \"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} Apart from t
he noise accuracy trade-off in privacy, there is one more problem known as “poor gets poorer”. This means t
hat if privacy mechanisms are not designed with proper balance and buyers and equity, the model may end up
discriminating between different user groups or users data. In other words, the noise which is added to the
 data may be proportional to the magnitude of the data point. So if this kind of noise is propagated into t
he model the data set may start collecting into groups of small sub data (as in unsupervised learning) and
the whole data set may end up looking like a collection of lumps of data at many different places on the gr
aph. Here lies another problem. User who contribute rare type of data, for example some users may like very
 rare genre of movies. If we apply equitable noise to the data set of all the users these rare contribution
s may for sure will get clocked in too much of noise and the system may not learn much about these rare dat
a set types and hence perform poorly. Because the whole point of Federated learning is to hide the raw data
 of the user, it is therefore almost impossible to tell whether the system is recommending content in all f
airness to all users or not. Privacy and fairness cannot go hand in hand at some instances. The simple fact
 that if privacy mechanisms and measures are not designed with fairness in mind, they can lead to harming m
inority group of users. Especially though group of users who contribute rare genre of data set. To resolve
this dilemma, we can deploy what is called “personalised privacy”. In this what happens is that the privacy
 protection is tailored to each user according to the data the user generates. This helps in keeping sensit
ive information of each user safe while at the same time system works efficiently and reliably from for eac
h user. A new strategy is proposed known as “multi objective optimization” to handle fairness and privacy t
ag of work and create a balance between all the groups so that no group of users is left behind with useles
s recommendations on their devices. This strategy has a goal to find an optimal point among accuracy, priva
cy and fairness, all at the same time. There are also some technical challenges like a privacy technique na
med Poisson subsampling which can put too much load on the low end mobile phones or hardware and their CPU.
 This will exclude users who possess older phones and hence will collect correct data from only users that
have high end specifications mobile phones and devices especially when they are new. Consequently the unfai
rness. This leads us to a warning named Matthew effect warning. It says that privacy if focused on while cr
eating a privacy system without bringing into the game fairness, then the resulting model of Federated lear
ning will reinforce or amplify already existing inequalities making the “poor even poorer”. (Badar et al.,

\"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} Apart from the noise accuracy trade-off in privacy, there is one more problem known as “poor gets poorer”. This means that if privacy mechanisms are not designed with proper balance and buyers and equity, the model may end up discriminating between different user groups or users data. In other words, the noise which is added to the data may be proportional to the magnitude of the data point. So if this kind of noise is propagated into the model the data set may start collecting into groups of small sub data (as in unsupervised learning) and the whole data set may end up looking like a collection of lumps of data at many different places on the graph. Here lies another problem. User who contribute rare type of data, for example some users may like very rare genre of movies. If we apply equitable noise to the data set of all the users these rare contributions may for sure will get clocked in too much of noise and the system may not learn much about these rare data set types and hence perform poorly. Because the whole point of Federated learning is to hide the raw data

 of the user, it is therefore almost impossible to tell whether the system is recommending content in all f
airness to all users or not. Privacy and fairness cannot go hand in hand at some instances. The simple fact
 that if privacy mechanisms and measures are not designed with fairness in mind, they can lead to harming m
inority group of users. Especially though group of users who contribute rare genre of data set. To resolve
this dilemma, we can deploy what is called “personalised privacy”. In this what happens is that the privacy
 protection is tailored to each user according to the data the user generates. This helps in keeping sensit
ive information of each user safe while at the same time system works efficiently and reliably from for eac
h user. A new strategy is proposed known as “multi objective optimization” to handle fairness and privacy t
ag of work and create a balance between all the groups so that no group of users is left behind with useles
s recommendations on their devices. This strategy has a goal to find an optimal point among accuracy, priva
cy and fairness, all at the same time. There are also some technical challenges like a privacy technique na
med Poisson subsampling which can put too much load on the low end mobile phones or hardware and their CPU.
 This will exclude users who possess older phones and hence will collect correct data from only users that
have high end specifications mobile phones and devices especially when they are new. Consequently the unfai
rness. This leads us to a warning named Matthew effect warning. It says that privacy if focused on while cr
eating a privacy system without bringing into the game fairness, then the resulting model of Federated lear
ning will reinforce or amplify already existing inequalities making the “poor even poorer”. (Badar et al.,

 rare genre of movies. If we apply equitable noise to the data set of all the users these rare contribution
s may for sure will get clocked in too much of noise and the system may not learn much about these rare dat
a set types and hence perform poorly. Because the whole point of Federated learning is to hide the raw data
 of the user, it is therefore almost impossible to tell whether the system is recommending content in all f
airness to all users or not. Privacy and fairness cannot go hand in hand at some instances. The simple fact
 that if privacy mechanisms and measures are not designed with fairness in mind, they can lead to harming m
inority group of users. Especially though group of users who contribute rare genre of data set. To resolve
this dilemma, we can deploy what is called “personalised privacy”. In this what happens is that the privacy
 protection is tailored to each user according to the data the user generates. This helps in keeping sensit
ive information of each user safe while at the same time system works efficiently and reliably from for eac
h user. A new strategy is proposed known as “multi objective optimization” to handle fairness and privacy t
ag of work and create a balance between all the groups so that no group of users is left behind with useles
s recommendations on their devices. This strategy has a goal to find an optimal point among accuracy, priva
cy and fairness, all at the same time. There are also some technical challenges like a privacy technique na
med Poisson subsampling which can put too much load on the low end mobile phones or hardware and their CPU.
 This will exclude users who possess older phones and hence will collect correct data from only users that
have high end specifications mobile phones and devices especially when they are new. Consequently the unfai
rness. This leads us to a warning named Matthew effect warning. It says that privacy if focused on while cr
eating a privacy system without bringing into the game fairness, then the resulting model of Federated lear
ning will reinforce or amplify already existing inequalities making the “poor even poorer”. (Badar et al.,

\"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} Apart from t
he noise accuracy trade-off in privacy, there is one more problem known as “poor gets poorer”. This means t
hat if privacy mechanisms are not designed with proper balance and buyers and equity, the model may end up
discriminating between different user groups or users data. In other words, the noise which is added to the
 data may be proportional to the magnitude of the data point. So if this kind of noise is propagated into t
he model the data set may start collecting into groups of small sub data (as in unsupervised learning) and
the whole data set may end up looking like a collection of lumps of data at many different places on the gr
aph. Here lies another problem. User who contribute rare type of data, for example some users may like very
 rare genre of movies. If we apply equitable noise to the data set of all the users these rare contribution
s may for sure will get clocked in too much of noise and the system may not learn much about these rare dat
a set types and hence perform poorly. Because the whole point of Federated learning is to hide the raw data
 of the user, it is therefore almost impossible to tell whether the system is recommending content in all f
airness to all users or not. Privacy and fairness cannot go hand in hand at some instances. The simple fact
 that if privacy mechanisms and measures are not designed with fairness in mind, they can lead to harming m
inority group of users. Especially though group of users who contribute rare genre of data set. To resolve
this dilemma, we can deploy what is called “personalised privacy”. In this what happens is that the privacy
 protection is tailored to each user according to the data the user generates. This helps in keeping sensit
ive information of each user safe while at the same time system works efficiently and reliably from for eac

\"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} Apart from t
he noise accuracy trade-off in privacy, there is one more problem known as “poor gets poorer”. This means t
hat if privacy mechanisms are not designed with proper balance and buyers and equity, the model may end up
discriminating between different user groups or users data. In other words, the noise which is added to the
data may be proportional to the magnitude of the data point. So if this kind of noise is propagated into t
he model the data set may start collecting into groups of small sub data (as in unsupervised learning) and
the whole data set may end up looking like a collection of lumps of data at many different places on the gr
aph. Here lies another problem. User who contribute rare type of data, for example some users may like very
rare genre of movies. If we apply equitable noise to the data set of all the users these rare contribution
s may for sure will get clocked in too much of noise and the system may not learn much about these rare dat

```
a set types and hence perform poorly. Because the whole point of Federated learning is to hide the raw data
 of the user, it is therefore almost impossible to tell whether the system is recommending content in all f
airness to all users or not. Privacy and fairness cannot go hand in hand at some instances. The simple fact
 that if privacy mechanisms and measures are not designed with fairness in mind, they can lead to harming m
inority group of users. Especially though group of users who contribute rare genre of data set. To resolve
this dilemma, we can deploy what is called “personalised privacy”. In this what happens is that the privacy
 protection is tailored to each user according to the data the user generates. This helps in keeping sensit
ive information of each user safe while at the same time system works efficiently and reliably from for eac
h user. A new strategy is proposed known as “multi objective optimization” to handle fairness and privacy t
ag of work and create a balance between all the groups so that no group of users is left behind with useles
s recommendations on their devices. This strategy has a goal to find an optimal point among accuracy, priva
cy and fairness, all at the same time. There are also some technical challenges like a privacy technique na
med Poisson subsampling which can put too much load on the low end mobile phones or hardware and their CPU.
 This will exclude users who possess older phones and hence will collect correct data from only users that
have high end specifications mobile phones and devices especially when they are new. Consequently the unfai
rness. This leads us to a warning named Matthew effect warning. It says that privacy if focused on while cr
eating a privacy system without bringing into the game fairness, then the resulting model of Federated lear
ning will reinforce or amplify already existing inequalities making the “poor even poorer”. (Badar et al.,

\"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} Apart from t
he noise accuracy trade-off in privacy, there is one more problem known as “poor gets poorer”. This means t
hat if privacy mechanisms are not designed with proper balance and buyers and equity, the model may end up
discriminating between different user groups or users data. In other words, the noise which is added to the
 data may be proportional to the magnitude of the data point. So if this kind of noise is propagated into t
he model the data set may start collecting into groups of small sub data (as in unsupervised learning) and
the whole data set may end up looking like a collection of lumps of data at many different places on the gr
aph. Here lies another problem. User who contribute rare type of data, for example some users may like very
 rare genre of movies. If we apply equitable noise to the data set of all the users these rare contribution
s may for sure will get clocked in too much of noise and the system may not learn much about these rare dat
a set types and hence perform poorly. Because the whole point of Federated learning is to hide the raw data
 of the user, it is therefore almost impossible to tell whether the system is recommending content in all f
airness to all users or not. Privacy and fairness cannot go hand in hand at some instances. The simple fact
 that if privacy mechanisms and measures are not designed with fairness in mind, they can lead to harming m
inority group of users. Especially though group of users who contribute rare genre of data set. To resolve
this dilemma, we can deploy what is called “personalised privacy”. In this what happens is that the privacy
 protection is tailored to each user according to the data the user generates. This helps in keeping sensit
ive information of each user safe while at the same time system works efficiently and reliably from for eac
h user. A new strategy is proposed known as “multi objective optimization” to handle fairness and privacy t
ag of work and create a balance between all the groups so that no group of users is left behind with useles
s recommendations on their devices. This strategy has a goal to find an optimal point among accuracy, priva
cy and fairness, all at the same time. There are also some technical challenges like a privacy technique na
med Poisson subsampling which can put too much load on the low end mobile phones or hardware and their CPU.
 This will exclude users who possess older phones and hence will collect correct data from only users that
have high end specifications mobile phones and devices especially when they are new. Consequently the unfai
rness. This leads us to a warning named Matthew effect warning. It says that privacy if focused on while cr
eating a privacy system without bringing into the game fairness, then the resulting model of Federated lear
ning will reinforce or amplify already existing inequalities making the “poor even poorer”. (Badar et al.,

\"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} Apart from t
he noise accuracy trade-off in privacy, there is one more problem known as “poor gets poorer”. This means t
hat if privacy mechanisms are not designed with proper balance and buyers and equity, the model may end up
discriminating between different user groups or users data. In other words, the noise which is added to the
 data may be proportional to the magnitude of the data point. So if this kind of noise is propagated into t
he model the data set may start collecting into groups of small sub data (as in unsupervised learning) and
the whole data set may end up looking like a collection of lumps of data at many different places on the gr
aph. Here lies another problem. User who contribute rare type of data, for example some users may like very
 rare genre of movies. If we apply equitable noise to the data set of all the users these rare contribution
s may for sure will get clocked in too much of noise and the system may not learn much about these rare dat
a set types and hence perform poorly. Because the whole point of Federated learning is to hide the raw data
 of the user, it is therefore almost impossible to tell whether the system is recommending content in all f
airness to all users or not. Privacy and fairness cannot go hand in hand at some instances. The simple fact
 that if privacy mechanisms and measures are not designed with fairness in mind, they can lead to harming m
inority group of users. Especially though group of users who contribute rare genre of data set. To resolve
this dilemma, we can deploy what is called “personalised privacy”. In this what happens is that the privacy
 protection is tailored to each user according to the data the user generates. This helps in keeping sensit
ive information of each user safe while at the same time system works efficiently and reliably from for eac
h user. A new strategy is proposed known as “multi objective optimization” to handle fairness and privacy t
ag of work and create a balance between all the groups so that no group of users is left behind with useles
s recommendations on their devices. This strategy has a goal to find an optimal point among accuracy, priva
cy and fairness, all at the same time. There are also some technical challenges like a privacy technique na
med Poisson subsampling which can put too much load on the low end mobile phones or hardware and their CPU.
 This will exclude users who possess older phones and hence will collect correct data from only users that
have high end specifications mobile phones and devices especially when they are new. Consequently the unfai
rness. This leads us to a warning named Matthew effect warning. It says that privacy if focused on while cr
eating a privacy system without bringing into the game fairness, then the resulting model of Federated lear
ning will reinforce or amplify already existing inequalities making the “poor even poorer”. (Badar et al.,

\"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} Apart from t
he noise accuracy trade-off in privacy, there is one more problem known as “poor gets poorer”. This means t
hat if privacy mechanisms are not designed with proper balance and buyers and equity, the model may end up
discriminating between different user groups or users data. In other words, the noise which is added to the
 data may be proportional to the magnitude of the data point. So if this kind of noise is propagated into t
he model the data set may start collecting into groups of small sub data (as in unsupervised learning) and
the whole data set may end up looking like a collection of lumps of data at many different places on the gr
aph. Here lies another problem. User who contribute rare type of data, for example some users may like very
 rare genre of movies. If we apply equitable noise to the data set of all the users these rare contribution
s may for sure will get clocked in too much of noise and the system may not learn much about these rare dat
a set types and hence perform poorly. Because the whole point of Federated learning is to hide the raw data
 of the user, it is therefore almost impossible to tell whether the system is recommending content in all f
airness to all users or not. Privacy and fairness cannot go hand in hand at some instances. The simple fact
 that if privacy mechanisms and measures are not designed with fairness in mind, they can lead to harming m
inority group of users. Especially though group of users who contribute rare genre of data set. To resolve
this dilemma, we can deploy what is called “personalised privacy”. In this what happens is that the privacy
 protection is tailored to each user according to the data the user generates. This helps in keeping sensit
ive information of each user safe while at the same time system works efficiently and reliably from for eac
h user. A new strategy is proposed known as “multi objective optimization” to handle fairness and privacy t
ag of work and create a balance between all the groups so that no group of users is left behind with useles
s recommendations on their devices. This strategy has a goal to find an optimal point among accuracy, priva
cy and fairness, all at the same time. There are also some technical challenges like a privacy technique na
med Poisson subsampling which can put too much load on the low end mobile phones or hardware and their CPU.
 This will exclude users who possess older phones and hence will collect correct data from only users that
have high end specifications mobile phones and devices especially when they are new. Consequently the unfai
rness. This leads us to a warning named Matthew effect warning. It says that privacy if focused on while cr
eating a privacy system without bringing into the game fairness, then the resulting model of Federated lear
ning will reinforce or amplify already existing inequalities making the “poor even poorer”. (Badar et al.,

\"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} Apart from t
he noise accuracy trade-off in privacy, there is one more problem known as “poor gets poorer”. This means t
hat if privacy mechanisms are not designed with proper balance and buyers and equity, the model may end up
discriminating between different user groups or users data. In other words, the noise which is added to the
 data may be proportional to the magnitude of the data point. So if this kind of noise is propagated into t
he model the data set may start collecting into groups of small sub data (as in unsupervised learning) and
the whole data set may end up looking like a collection of lumps of data at many different places on the gr
aph. Here lies another problem. User who contribute rare type of data, for example some users may like very
 rare genre of movies. If we apply equitable noise to the data set of all the users these rare contribution
s may for sure will get clocked in too much of noise and the system may not learn much about these rare dat
a set types and hence perform poorly. Because the whole point of Federated learning is to hide the raw data
 of the user, it is therefore almost impossible to tell whether the system is recommending content in all f
airness to all users or not. Privacy and fairness cannot go hand in hand at some instances. The simple fact
 that if privacy mechanisms and measures are not designed with fairness in mind, they can lead to harming m
inority group of users. Especially though group of users who contribute rare genre of data set. To resolve
this dilemma, we can deploy what is called “personalised privacy”. In this what happens is that the privacy
 protection is tailored to each user according to the data the user generates. This helps in keeping sensit
ive information of each user safe while at the same time system works efficiently and reliably from for eac
h user. A new strategy is proposed known as “multi objective optimization” to handle fairness and privacy t
ag of work and create a balance between all the groups so that no group of users is left behind with useles
s recommendations on their devices. This strategy has a goal to find an optimal point among accuracy, priva
cy and fairness, all at the same time. There are also some technical challenges like a privacy technique na
med Poisson subsampling which can put too much load on the low end mobile phones or hardware and their CPU.
 This will exclude users who possess older phones and hence will collect correct data from only users that
have high end specifications mobile phones and devices especially when they are new. Consequently the unfai
rness. This leads us to a warning named Matthew effect warning. It says that privacy if focused on while cr
eating a privacy system without bringing into the game fairness, then the resulting model of Federated lear
ning will reinforce or amplify already existing inequalities making the “poor even poorer”. (Badar et al.,

\"schema\":\"https://github.com/citation-style-language/schema/raw/master/csl-citation.json\"} Apart from the noise accuracy trade-off in privacy, there is one more problem known as “poor gets poorer”. This means that if privacy mechanisms are not designed with proper balance and buyers and equity, the model may end up discriminating between different user groups or users data. In other words, the noise which is added to the data may be proportional to the magnitude of the data point. So if this kind of noise is propagated into the model the data set may start collecting into groups of small sub data (as in unsupervised learning) and the whole data set may end up looking like a collection of lumps of data at many different places on the graph. Here lies another problem. User who contribute rare type of data, for example some users may like very rare genre of movies. If we apply equitable noise to the data set of all the users these rare contributions may for sure will get clocked in too much of noise and the system may not learn much about these rare data set types and hence perform poorly. Because the whole point of Federated learning is to hide the raw data of the user, it is therefore almost impossible to tell whether the system is recommending content in all fairness to all users or not. Privacy and fairness cannot go hand in hand at some instances. The simple fact that if privacy mechanisms and measures are not designed with fairness in mind, they can lead to harming minority group of users. Especially though group of users who contribute rare genre of data set. To resolve this dilemma, we can deploy what is called “personalised privacy”. In this what happens is that the privacy protection is tailored to each user according to the data the user generates. This helps in keeping sensitive information of each user safe while at the same time system works efficiently and reliably from for each user. A new strategy is proposed known as “multi objective optimization” to handle fairness and privacy tag of work and create a balance between all the groups so that no group of users is left behind with useless recommendations on their devices. This strategy has a goal to find an optimal point among accuracy, privacy and fairness, all at the same time. There are also some technical challenges like a privacy technique named Poisson subsampling which can put too much load on the low end mobile phones or hardware and their CPU. This will exclude users who possess older phones and hence will collect correct data from only users that have high end specifications mobile phones and devices especially when they are new. Consequently the unfai

rness. This leads us to a warning named Matthew effect warning. It says that privacy if focused on while cr
eating a privacy system without bringing into the game fairness, then the resulting model of Federated lear
ning will reinforce or amplify already existing inequalities making the “poor even poorer”. (Badar et al.,
